(57) ABSTRACT

Liquid crystal display backplane layouts and addressing for non-standard subpixel arrangements are disclosed. A liquid crystal display comprises a panel and a plurality of transistors. The panel substantially comprises a subpixel repeating group having an even number of subpixels in a first direction. Each thin film transistor connects one subpixel to a row and a column line at an intersection in one of a group of quadrants. The group comprises a first quadrant, a second quadrant, a third quadrant and a fourth quadrant, wherein the thin film transistors are formed in a backplane structure adjacent to intersections of the row and column lines. The thin film transistors are also substantially formed in more than one quadrant in the backplane structure.

FIG. 18 (PRIOR ART)

LIQUID CRYSTAL DISPLAY BACKPLANE LAYOUTS AND ADDRESSING FOR NON-STANDARD SUBPIXEL ARRANGEMENTS

This application is a continuation of U.S. patent application Ser. No. 10/456,838, filed on Jun. 6, 2003, and claims the benefit of priority thereof and is now issued as U.S. Pat. No. 7,397,455 which is hereby incorporated by reference.

RELATED APPLICATIONS

The present application is related to commonly owned (and filed on even date) United States Patent Applications: (1) United States Patent Publication No. 2004/0246213 ("the 15 '213 application") U.S. patent application Ser. No. 10/455, 925 entitled "DISPLAY PANEL HAVING CROSSOVER CONNECTIONS EFFECTING DOT INVERSION"; (2) U.S. Pat. No. 7,218,301 ("the '301 patent") U.S. patent application Ser. No. 10/455,931 entitled "SYSTEM AND 20 METHOD OF PERFORMING DOT INVERSION WITH STANDARD DRIVERS AND BACKPLANE ON NOVEL DISPLAY PANEL LAYOUTS"; (3) U.S. Pat. No. 7,209,105 ("the '105 patent") U.S. patent application Ser. No. 10/455, 927 entitled "SYSTEM AND METHOD FOR COMPEN- 25 SATING FOR VISUAL EFFECTS UPON PANELS HAV-ING FIXED PATTERN NOISE WITH REDUCED QUANTIZATION ERROR"; (4) U.S. Pat. No. 7,187,353 ("the '353 patent") U.S. patent application Ser. No. 10/456, 806 entitled "DOT INVERSION ON NOVEL DISPLAY 30 PANEL LAYOUTS WITH EXTRA DRIVERS"; and (5) United States Patent Publication No. 2004/0246280 ("the '280 application") U.S. patent application Ser. No. 10/456, 839 entitled "IMAGE DEGRADATION CORRECTION IN NOVEL LIQUID CRYSTAL DISPLAYS," which are hereby 35 incorporated herein by reference.

BACKGROUND

In commonly owned United States Patent Applications: (1) 40 U.S. Pat. No. 6,903,754 ("the '754 patent") U.S. patent application Ser. No. 09/916,232 entitled "ARRANGEMENT OF COLOR PIXELS FOR FULL COLOR IMAGING DEVICES WITH SIMPLIFIED ADDRESSING," filed Jul. 25, 2001; (2) United States Patent Publication No. 2003/ 45 0128225 ("the '225 application") U.S. patent application Ser. No. 10/278,353 entitled "IMPROVEMENTS TO COLOR FLAT PANEL DISPLAY SUB-PIXEL ARRANGEMENTS AND LAYOUTS FOR SUB-PIXEL RENDERING WITH INCREASED MODULATION TRANSFER FUNCTION 50 RESPONSE," filed Oct. 22, 2002; (3) United States Patent Publication No. 2003/0128179 ("the '179 application") U.S. patent application Ser. No. 10/278,352, entitled "IMPROVE-MENTS TO COLOR FLAT PANEL DISPLAY SUB-PIXEL ARRANGEMENTS AND LAYOUTS FOR SUB-PIXEL 55 RENDERING WITH SPLIT BLUE SUB-PIXELS," filed Oct. 22, 2002; (4) United States Patent Publication No. 2004/ 0051724 ("the '724 application") U.S. patent application Ser. No. 10/243,094, entitled "IMPROVED FOUR COLOR ARRANGEMENTS AND EMITTERS FOR SUB-PIXEL 60 RENDERING," filed Sep. 13, 2002; (5) United States Patent Publication No. 2003/0117423 ("the '423 application") U.S. patent application Ser. No. 10/278,328, entitled "IMPROVE-MENTS TO COLOR FLAT PANEL DISPLAY SUB-PIXEL ARRANGEMENTS AND LAYOUTS WITH REDUCED 65 BLUE LUMINANCE WELL VISIBILITY," filed Oct. 22, 2002; (6) U.S. Pat. No. 7,283,142 ("the '142 patent") U.S.

2

patent application Ser. No. 10/278,393, entitled "COLOR DISPLAY HAVING HORIZONTAL SUB-PIXEL ARRANGEMENTS AND LAYOUTS," filed Oct. 22, 2002; (7) United States Patent Publication No. 2004/0080479 ("the '479 application") U.S. patent application Ser. No. 10/347, 001 entitled "IMPROVED SUB-PIXEL ARRANGEMENTS FOR STRIPED DISPLAYS AND METHODS AND SYSTEMS FOR SUB-PIXEL RENDERING SAME," filed Jan. 16, 2003, novel sub-pixel arrangements are therein disclosed for improving the cost/performance curves for image display devices and herein incorporated by reference.

These improvements are particularly pronounced when coupled with sub-pixel rendering (SPR) systems and methods further disclosed in those applications and in commonly owned United States Patent Applications: (1) U.S. Pat. No. 7,123,277 ("the '277 patent") U.S. patent application Ser. No. 10/051,612, entitled "CONVERSION OF A SUB-PIXEL FORMAT DATA TO ANOTHER SUB-PIXEL DATA FOR-MAT," filed Jan. 16, 2002; (2) U.S. Pat. No. 7,221,381 ("the '381 patent") U.S. patent application Ser. No. 10/150,355, entitled "METHODS AND SYSTEMS FOR SUB-PIXEL RENDERING WITH GAMMA ADJUSTMENT," filed May 17, 2002; (3) U.S. Pat. No. 7,184,066 ("the '066 patent") U.S. patent application Ser. No. 10/215,843, entitled "METHODS AND SYSTEMS FOR SUB-PIXEL RENDERING WITH ADAPTIVE FILTERING," filed Aug. 8, 2002; (4) United States Patent Publication No. 2004/0196302 ("the '302 application") U.S. patent application Ser. No. 10/379,767, entitled "SYSTEMS AND METHODS FOR TEMPORAL SUB-PIXEL RENDERING OF IMAGE DATA" filed Mar. 4, 2003; (5) U.S. Pat. No. 7,167,186 ("the '186 patent") U.S. patent application Ser. No. 10/379,765, entitled "SYSTEMS AND METHODS FOR MOTION ADAPTIVE FILTERING," filed Mar. 4, 2003; (6) U.S. Pat. No. 6,917,368 ("the '368 patent") U.S. patent application Ser. No. 10/379,766 entitled "SUB-PIXEL RENDERING SYSTEM AND METHOD FOR IMPROVED DISPLAY VIEWING ANGLES" filed Mar. 4, 2003; (7) U.S. Pat. No. 7,352,374 ("the '374 patent") U.S. patent application Ser. No. 10/409,413 entitled "IMAGE DATA SET WITH EMBEDDED PRE-SUBPIXEL REN-DERED IMAGE" filed Apr. 7, 2003, which are hereby incorporated herein by reference.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in, and constitute a part of this specification illustrate exemplary implementations and embodiments of the invention and, together with the description, serve to explain principles of the invention.

FIG. 1A shows a conventional RGB stripe panel with 1×1 dot inversion.

FIG. 1B shows a conventional RGB stripe panel with 1×2 dot inversion.

FIG. 2 shows a panel having a novel subpixel repeating group of even number of subpixels in a first (row) direction with a conventional 1×1 dot inversion scheme.

FIG. 3 shows the panel of FIG. 2 with a novel TFT backplane layout.

FIG. 4 depicts the operation of the panel of FIG. 3 during two row-writes.

FIG. 5 depicts another embodiment of a TFT backplane layout with a 1×1 dot inversion scheme.

FIG. 6 depicts the panel of FIG. 5 with a 1×2 dot inversion scheme

FIG. 7 depicts a panel wherein at least two regions are defined with TFTs constructed in the a first region of a pixel and TFTs constructed in a second region of a pixel.

FIGS. **8** through **15** depict a general technique for remapping TFT to a backplane layout so as to effect a desired dot inversion scheme on a panel having a novel subpixel repeating group.

FIGS. **16**A and **16**B show a particular embodiment of a TFT backplane layout on a panel having a novel subpixel repeating group with a 1×2 dot inversion scheme.

FIG. 16C shows yet another embodiment of a TFT backplane layout with a novel subpixel repeating group affecting a 1×2 dot inversion scheme.

FIGS. 17A, 17B, and 17C show particular TFTs having a double source/drain structure.

FIG. 18 shows a TFT with a double gate structure.

FIGS. **19**A and **19**B show TFT structures in a normal orientation and a reverse orientation respectively.

FIGS. **20**A and **20**B show TFT structures in a normal orientation and a reverse orientation with an added gate cross-over in the normal orientation to balance any parasitic capacitance found in the reverse orientation.

FIGS. **21**A and **21**B show TFT structures in a normal orientation and a reverse orientation with one fewer gate crossover in the reverse orientation to match any parasitic ²⁵ capacitance in the normal orientation.

FIG. 22 shows one novel pixel element design having a corner removed from the pixel to balance parasitic capacitances.

FIG. 23 shows yet another novel pixel element design ³⁰ having multiple corners removed to balance parasitic capacitances.

FIG. 24 shows yet another novel pixel structure in which at least one extra line is added to shield the pixel element from parasitic effects.

DETAILED DESCRIPTION

Reference will now be made in detail to implementations and embodiments, examples of which are illustrated in the 40 accompanying drawings. Wherever possible, the same reference numbers will be used throughout the drawings to refer to the same or like parts.

FIG. 1A shows a conventional RGB stripe structure on panel 100 for an Active Matrix Liquid Crystal Display (AM-45 LCD) having thin film transistors (TFTs) 116 to activate individual colored subpixels—red 104, green 106 and blue 108 subpixels respectively. As may be seen, a red, a green and a blue subpixel form a repeating group of subpixels 102 that comprise the panel.

As also shown, each subpixel is connected to a column line (each driven by a column driver 110) and a row line (e.g. 112 and 114). In the field of AMLCD panels, it is known to drive the panel with a dot inversion scheme to reduce crosstalk and flicker. FIG. 1A depicts one particular dot inversion 55 scheme—i.e. 1×1 dot inversion—that is indicated by a "+" and a "-" polarity given in the center of each subpixel. Each row line is typically connected to a gate (not shown in FIG. 1A) of TFT 116. Image data—delivered via the column lines—are typically connected to the source of each TFT. 60 Image data is written to the panel a row at a time and is given a polarity bias scheme as indicated herein as either ODD ("O") or EVEN ("E") schemes. As shown, row 112 is being written with ODD polarity scheme at a given time while row 114 is being written with EVEN polarity scheme at a next 65 time. The polarities alternate ODD and EVEN schemes a row at a time in this 1×1 dot inversion scheme.

4

FIG. 1B depicts another conventional RGB stripe panel having another dot inversion scheme—i.e. 1×2 dot inversion. Here, the polarity scheme changes over the course of two rows—as opposed to every row, as in 1×1 dot inversion. In both dot inversion schemes, a few observations are noted: (1) in 1×1 dot inversion, every two physically adjacent subpixels (in both the horizontal and vertical direction) are of different polarity; (2) in 1×2 dot inversion, every two physically adjacent subpixels in the horizontal direction are of different polarity; (3) across any given row, each successive colored subpixel has an opposite polarity to its neighbor. Thus, for example, two successive red subpixels along a row will be either (+,-) or (-,+). Of course, in 1×1 dot inversion, two successive red subpixels along a column with have opposite polarity; whereas in 1×2 dot inversion, each group of two successive red subpixels will have opposite polarity. This changing of polarity decreases noticeable visual defects that occur with particular images rendered upon an AMLCD

FIG. 2 shows a panel comprising a repeat subpixel grouping 202, as further described in the '353 application. As may be seen, repeat subpixel grouping 202 is an eight subpixel repeat group, comprising a checkerboard of red and blue subpixels with two columns of reduced-area green subpixels in between. If the standard 1×1 dot inversion scheme is applied to a panel comprising such a repeat grouping (as shown in FIG. 2), then it becomes apparent that the property described above for RGB striped panels (namely, that successive colored pixels in a row and/or column have different polarities) is now violated. This condition may cause a number of visual defects noticed on the panel—particularly when certain image patterns are displayed. This observation also occurs with other novel subpixel repeat grouping-for example, the subpixel repeat grouping in FIG. 1 of the '352 35 application—and other repeat groupings that are not an odd number of repeating subpixels across a row. Thus, as the traditional RGB striped panels have three such repeating subpixels in its repeat group (namely, R, G and B), these traditional panels do not necessarily violate the above noted conditions. However, the repeat grouping of FIG. 2 in the present application has four (i.e. an even number) of subpixels in its repeat group across a row (e.g. R, G, B, and G). It will be appreciated that the embodiments described herein are equally applicable to all such even modulus repeat groupings.

In order to affect improved performance, several embodiments are herein described. A first embodiment of an AMLCD panel 300 is shown in FIG. 3. Box 302 encloses four TFTs 116 that drive their associated four colored subpixels. As may be seen, the gates of each TFT 116 are connected to 50 a row line in such a manner as to have same colored subpixels—successively staggered—across each row affect opposite polarity. This effect is shown in FIG. 4, for example, with red subpixels 408, 410, and 412, etc. receiving $(-, +, -, \dots)$ polarities during a row write to line 404. The same effect is shown for blue subpixels across line 404. One possible benefit of this condition is that any parasitic capacitances (for example, as between the gate and the drain of the TFT, CGD, and as between the pixel and the gate line, CG-Pixel.) that occur across a row/gate line with are minimized by having the same number of "+" and "-" polarities connected to the row/gate line.

It is further seen in FIG. 3 that the TFTs 116 in repeating group 302 are formed at the intersection of a pair of row and column lines at a given quadrant of the subpixel. For example, the upper red subpixel in group 302 has its TFT formed in the first quadrant; while the upper green subpixel has its TFT formed in the third quadrant. To affect a dot inversion scheme

on a subpixel repeating group of an even number of subpixels in a row or column direction, one embodiment is to find a suitable remapping of the TFT backplane from their usual placement in one quadrant, so that the remapping may use any number of quadrants greater than one.

FIG. 4 depicts how panel 300 operates over the course of two successive row-writes. During the first row-write (panel 300 on the left hand side), row 402 sends an active gate signal down to the connected TFTs and their associated subpixels (shown in BOLD hatching) on an EVEN cycle. In this case, 10 all of the green subpixels in two rows are activated. However, as may be seen, the TFTs have been advantageously replaced so that two bordering green subpixels in the vertical direction have opposite polarities. So, for example, green subpixel 406 has a "+" polarity; while green subpixel 408 has a "-" polarity. Additionally, as may be seen, the polarities of all of the green subpixels connected to row line 402 are balanced—i.e. the number of "+" polarity green subpixels equals the number of "-" polarity green subpixels.

During the next row-write (as shown in panel 300 on the 20 right hand side), row line 404 sends an active gate signal to its connected TFTs and their associated subpixels (also shown in BOLD hatching) on an ODD cycle. Again, given the replacement of the TFTs, each two adjacent subpixels in the vertical direction have opposite polarity. Additionally, as described 25 above, same colored subpixels that are successively staggered along a row line are of opposite polarity.

Yet another embodiment comprising a TFT replacement (i.e. off from the traditional manner of consistently placing TFTs in a single position relative to the subpixels —such as 30 the upper left hand corner) is shown in FIG. 5. The repeat grouping of TFTs in this arrangement are shown as block 502. With this arrangement, similar corrective polarity conditions as noted for FIGS. 3 and 4 are found with the TFT placement of FIG. 5. For example, along row/gate line 504, every two red 35 subpixels alternate polarity—e.g. red subpixels 510 and 512 have "+" polarity; while red subpixels 514 and 516 have "-" polarity. As will be discussed in greater detail below, there are a number of different TFT placements that will achieve the same effects. Each such TFT placement (or TFT "remap- 40 ping") is contemplated within the scope of the present invention and, as such, the present invention should not be limited to any particular TFT placement or remapping.

FIG. 6 is yet another embodiment of TFT remapping on panel 600 that may take into account additional parasitic 45 capacitance effects between pixel and the CS electrode 602. In this case, two successive row/gate lines are driven by a given polarity scheme (O or E). The polarity of each subpixel is shown in its center. It will be noted that along any given row (and hence along a given CS line), successive same colored 50 subpixels alternate polarity.

Another TFT remapping that may produce similar beneficial effects is shown in FIG. 7. In this case, the panel 700 is partitioned into sections (e.g. 702, 704) that place the TFTs of their associated subpixels in corners such that the polarity at 55 the two columns at the partition line repeats. Thus, for example, column 710 and 712 have the same polarities of subpixels going down the respective columns. If the number of subpixels across a row defining a given partition is small enough, the accumulated parasitic capacitances in that partition may be sufficiently below a visually detectable (or at least manageable) level. This partitioning across a panel might occur a number of times in order to keep those parasitics at a low enough level. As an alternative embodiment, this panel could have a 1×2 dot inversion scheme—thereby effectively 65 solving vertical crosstalk (i.e. whereby same colored subpixels have same polarity in a given column).

6

FIGS. **8** through **15** outline a general procedure for developing many different embodiments of TFT remappings that may effect reduced parasitic capacitance in an panel having even modulus for a subpixel repeating group. Starting with a basic grid **800** of FIG. **8**, a repeating subpixel grouping **902** is placed upon the grid in FIG. **9**. It will be appreciated that, as noted above, any repeating group would suffice here; but preferably one with an even number of subpixels across a row. A dot inversion scheme is selected in FIG. **10**—in this case, a 1×2 dot inversion scheme is selected with two polarity schemes or "phases" —O and E. Additionally, these two phases are repeated for every two row/gate lines—O, O, E, E, etc. If 1×1 dot inversion were desired, then the phases would alternate every row/gate line.

Any symmetries in the repeat grouping are now to be considered. For example, in FIG. 11, it is noted that every other column is a line of blue subpixels. Thus, a possible symmetry to consider is in the other columns of alternating red and green subpixels. Now, consider all possible combinations of polarities for the first two subpixels in the columns of interest. In FIG. 11 for example, the first two red and green subpixels could assume a set of four possible polarity values. In general, if the first N subpixels in relevant rows or columns are considered, then 2N combinations of polarities may or should be considered.

Other symmetries may also be taken into consideration. In FIG. 12, the polarities in one of the columns of same colored subpixels are considered. A listing of possible polarities are shown in list 1202 for the second column of blue subpixels—and the first four such blue subpixels in the column are considered. The list could be exhaustive of the possibilities of polarities and certainly another number other than four may be considered. As it may be advantageous to balance the polarities down a given column—all of those possibilities with a balanced number of polarities are noted as "OK". One OK combination 1204 is selected, solely for exemplary purposes, for grid 1206.

FIG. 13 shows an initial selection of TFT placements on the grid. Initially, for optional visual aiding, the polarities accorded to each intersection of a row/gate line and a column/ data line are placed on the grid—as either a "+" or a "-". It is noted that any TFT placed in any quadrant around an intersection point will effect the same polarity on its associated subpixel. As for the subpixels in FIG. 12 that have been assigned a polarity, there is a degree of freedom in selecting which intersection to place the TFT. For example, red subpixel 1302 has been assigned a "+" polarity and there are two possible intersections 1304 and 1306 at which to place its associated TFT. For exemplary purposes, the TFT is selected to be placed at intersection 1304. Of course, the placement of TFTs could be affected by many possible factors—for example, the desire to minimally impact design rules, to minimize ill effect (e.g. parasitic capacitances), etc. As may be seen, the other TFTs for the polarity-assigned subpixels in FIG. 13 have also been placed—as one possible embodiment and selection thereof. Of course, other embodiments/selections are also possible.

FIG. 14 extends this process of TFT placement to the remaining blue subpixels on the grid. Although there are other selections possible, this particular selection was made with the idea of balancing the polarities across any given row. As may be seen, the blue subpixels polarities balance out across any given row/gate line. FIG. 15 fills in the remaining red and green subpixel TFT placements. One possible goal is to assign the remaining TFTs in a grouping that may be repeated across the entire panel to form the backplane. One such repeat grouping is 1502 in FIG. 15. Grouping 1502 is an 8×4 sub-

pixel grouping that seeks to balance polarities across all subpixels in the row and column directions, as well as balancing polarities within each single color subpixel sub-gird in the row and column directions. It will be appreciated that by following the general procedure outlined above and exploiting the various degrees of freedom in design choice, many possible TFT placements or remappings are possible to develop a suitable TFT grid.

FIG. 16A shows one possible TFT remapping grid effecting a 1×2 dot inversion scheme. FIG. 16B shows how the remapping grid might be implemented on a panel with a little greater detail. TFT 1602 and 1604—with TFT 1602 implemented at the bottom of a pixel area and TFT 1604 at the top of a pixel area—are possibly susceptible to some uneven effects that might be introduced during the manufacturing process. For example, if the gate metal or pixel electrode masks are translated upwards during manufacturing, then it may be possible for reduced parasitic capacitance for TFT 1602 and its associated pixel and for increased parasitic 20 capacitance for TFT 1604 and its associated pixel. If the errors in parasitics are out of tolerance bounds, then the yield of manufacturing such panels with unconventional TFT remappings might decrease. Thus, it may desirable to redesign the TFT structure as described below in order to abate 25 any uneven effects as noted above.

FIG. **16**C shows another embodiment of a panel having a novel subpixel repeating group **1650**. In this group, the pattern looks like:

RGBG

RGBG

BGRG

BGRG

When a 1×1 dot inversion scheme is applied to this repeat grouping, vertical crosstalk problems are solved. Addition- 35 ally, all the TFTs may be place on the same side of the pixel structure—which may reduce some parasitic effects or imbalances.

One known attempt to correct for TFT misalignments and any associated increase in parasitic capacitance is found in 40 U.S. Pat. No. 5,191,451 to Katayama et al. FIG. 17A depicts the "double TFT" arrangement 1700 of the '451 patent. Source line 1704 connects to the TFT via source electrode 1706. Two gate electrodes 1708 are connected to gate line 1702. Two drain electrodes 1710 connect to the pixel and are 45 formed such that the two gate electrodes 1708 affect conduction from the source electrode to the drain electrodes when activated. It is noted that there are two crossover regions 1712 that are connected to TFT may produce additional parasitic capacitance between the gate and the source. As discussed in 50 the '451 patent, any vertical misalignment of the TFT placement is somewhat corrected by this double TFT arrangement as is discussed therein. FIGS. 17B and 17C provide different alternative embodiments for the double TFT structure to the one shown in FIG. 17A. This structure will enable reduced 55 source to gate capacitance, which can cause crosstalk in certain images. The gate to drain crossover will be less damaging to image quality. One advantage of the embodiment of FIG. 17C is that there is only one crossover 1732 that may reduce parasitic capacitance.

Another manner of reducing the ill effects of TFT misalignment is shown in U.S. Pat. No. 5,097,297 to Nakazawa. FIG. 18 depicts a TFT 1800 made in the manner taught in the '297 patent. As may be seen in FIG. 18, gate line 1802 delivers the gate signal to gate electrode 1808. Source line 1804 sends 65 image data to source electrodes 1806. When the gate electrode is activated, the image data is transferred to the pixel via

8

the drain electrode **1810**. It is noted that this TFT embodiment contains only one gate crossover **1812** which aids in reducing parasitic capacitance.

Another set of TFT redesigns are shown in FIGS. 19
through 21 to handle the unevenness of parasitic capacitance that might be introduced by the above described TFT remapping. As TFTs are remapped on the panel, it is possible for some TFTs on the panel to be implemented in different corners or quadrants of a pixel area. For example, some TFTs may be constructed in the upper left hand corner of the pixel area, some in the upper right hand corner of the pixel area and so on. If all such TFTs were constructed the same way, then it would be likely that the source-drain orientation would be reversed for left hand corner and right hand corner implementation. Such non-uniformity of construction might introduce uneven parasitic capacitance in the case of a given TFT misalignment.

FIG. 19 is one embodiment of a TFT built with a reverse orientation 1902 as compared with a TFT built with a typical orientation 1904. For exemplary purposes, TFT 1904 is constructed within the upper left hand corner of its associated pixel in the usual manner—i.e. without any crossovers to avoid any introduced parasitic capacitance. It is noted that the source (S) and drain (D) electrodes are placed in a left-to-right fashion. TFT 1902 is shown constructed in the upper right hand corner of a pixel area in a reverse orientation—i.e. a crossover 1914 from source line 1906 is constructed so that the source electrode 1910 and drain electrode 1912 are also in left-to-right fashion. Thus, if there is a TFT misalignment in 30 the horizontal direction, then TFTs 1902 and 1904 will receive the same amount of added parasitic capacitancethus, keeping the panel's defects uniform. It will be appreciated that although TFT 1902 and TFT 1904 are depicted side-by-side and connected to the same column, this is primarily for explanatory purposes. It is unlikely that two adjoining subpixels would share the same column/data line—thus, TFT 1904 and its associated pixel is provided to show the distinction between a normal TFT orientation and TFT 1902 in a reverse orientation.

FIG. 20 shows another embodiment of TFTs 1902 and 1904. As can be seen, a new crossover 2002 is added to TFT 1904 so as to balance the added parasitic capacitance via crossover 1914. FIG. 21 is yet another embodiment of TFTs 1902 and 1904. As may be seen here, the gate electrode crossover 1914 has been removed in favor of a gate line crossover 2102 which may have a lesser impact on individual pixel elements.

FIGS. 22 and 23 are embodiments of pixel elements with corners 2210 and 2310 removed to match the one corner removed containing the TFT structure. These pixel elements as designed here may balance the parasitic capacitances more than a normal pixel structure.

FIG. 24 is another embodiment of a pixel structure that employs at least one extra metal line 2410 that may help to shield the pixel element from the parasitic capacitances between the gate lines and the pixel element. Additionally, if a dot inversion scheme is employed, then the opposing polarities on both lines 2410 will also help to balance any parasitic capacitance between the source lines and the pixel elements.

What is claimed is:

- 1. A liquid crystal display comprising:
- a display panel substantially comprising a plurality of a subpixel repeating group; the subpixel repeating group comprises at least two rows, each of said rows further comprising an even number of subpixels; wherein each row of subpixels comprises at least two same-colored subpixels;

each said subpixel having an associated thin film transistor (TFT) connected to a row line and a column line; said thin film transistor being formed in a corner of said subpixel in one of a group of quadrants with respect to said subpixel, the group comprising a first quadrant, a 5 second quadrant, a third quadrant and a fourth quadrant; driver circuitry configured to send image signals and polarity signals to said subpixels; and

wherein said display panel is partitioned into a plurality of sections along a row direction wherein said subpixels in each at a first section have their associated TFTs in a first quadrant and said subpixels in a second section have their TFTs in a second quadrant such that the polarity signal sent to same colored subpixels in said first section are different from polarity signals sent to same colored 15 subpixels in said second section.

- 2. The liquid crystal display of claim 1 wherein said polarity signal comprises a 1×1 dot inversion polarity signal.
- 3. The liquid crystal display of claim 1 wherein said polarity signal comprises a 1×2 dot inversion polarity signal.
- 4. The liquid crystal display of claim 1 wherein the partitioning of said display panel occurs with frequency across said row direction such that parasitic capacitance effects are substantially abated.
- 5. The liquid crystal display of claim 1, wherein said sub- 25 pixels in said first section are connected to an odd-numbered column line, and said subpixels in said second section are connected to an even-numbered column line.
- 6. The liquid crystal display of claim 1, wherein said subpixels in said first section are connected to an even-numbered 30 column line, and said subpixels in said second section are connected to an odd-numbered column line.
- 7. The liquid crystal display of claim 1, wherein said subpixel repeating group comprises a first subpixel having a first color, a second subpixel having a second color different from 35 the first color, a third color subpixel having a third color different from the first and second colors and a fourth subpixel having the third color in each of said rows.
- 8. The liquid crystal display of claim 7, wherein the first
- 9. The liquid crystal display of claim 7, wherein the third subpixel has a size smaller than each of the first subpixel and the second subpixel, and the fourth subpixel has a size substantially the same as the third subpixel.

10

- 10. The liquid crystal display of claim 7, wherein the first subpixel in a first row and the second subpixel in a second row are disposed in a same column.
- 11. The liquid crystal display of claim 10, wherein the third subpixel in a first row and the third subpixel in a second row are disposed in a same column.
- 12. The liquid crystal display of claim 11, wherein the third subpixel of the first row is disposed between the first and second subpixels, and the second subpixel of the first row is disposed between the third and fourth subpixels.
- 13. The liquid crystal display of claim 12, wherein the first and second subpixels of the first row are connected to a first row line, and the third and fourth subpixels of the first row are connected to a second row line.
- 14. The liquid crystal display of claim 13, wherein the third and fourth subpixels of the second row are connected to the first row line, and the first and second subpixels of the second row are connected to a third row line.
- 15. The liquid crystal display of claim 12, wherein the first 20 subpixel of the first row is connected to a first column line, and the second subpixel of the second row, which is disposed in the same column as the first subpixel of the first row, is connected to a second column line.
 - 16. The liquid crystal display of claim 15, wherein the third subpixel of the second row is connected to the second column line, and the third subpixel of the first row, which is disposed in the same column as the third subpixel of the second row, is connected to a third column line.
 - 17. The liquid crystal display of claim 12, wherein the first and third subpixels of the first row are connected to a first row line, and the second and fourth subpixels of the first row are connected to a second row line.
 - 18. The liquid crystal display of claim 7, wherein the first subpixel in a first row and the first subpixel in a second row are disposed in a same column.
 - 19. The liquid crystal display of claim 18, wherein the third subpixel in a first row and the third subpixel in a second row are disposed in a same column.
- 20. The liquid crystal display of claim 19, wherein the third color is red, the second color is green and the third color is 40 subpixel of the first row is disposed between the first and second subpixels, and the second subpixel of the first row is disposed between the third and fourth subpixels.
