ABSTRACT

An arrangement for a high resolution active matrix display includes organic emissive layers of distinct colors each deposited across continuous regions so as to include more than one pixel emissive region. Color filters are situated to partially block light from at least some of the emissive regions such that primary additive colors are transmitted from distinct subsets of pixels. The emissive layers may be deposited in alternating parallel stripes along rows or columns of the display, or may be oriented perpendicularly with respect to one another such that the emissive layers overlap in the emissive regions of at least some pixels. In some examples, red, green, and blue of pixels are arranged in regular patterns across the display and with the emissive regions for the blue pixels forming a relatively larger area of the display than either the red or green pixels.

HIGH RESOLUTION DISPLAY ARCHITECTURE

FIELD OF THE INVENTION

[0001] The present disclosure generally relates to flat panel displays formed by controllably depositing materials on a substrate and systems and methods for manufacturing such displays, and, more particularly, to organic light emitting diode displays where light emissive layers are deposited on a display substrate through a shadow mask.

BACKGROUND

[0002] Displays can be created from an array of organic light emitting devices ("OLEDs") each controlled by individual circuits (i.e., pixel circuits) having transistors for selectively controlling the circuits to be programmed with display information and to emit light according to the display information. Thin film transistors ("TFTs") fabricated on a substrate can be incorporated into such pixel circuits.

[0003] Generally, such pixel circuits include a drive transistor that conveys current through an organic emissive layer. Light is generated within the emissive layer due to recombination of holes and electrons passing through the layer in opposite directions. Accordingly, the intensity of emitted light is controlled by the amount of current flowing through the emissive layer, and the color of the emitted light is determined by the energy transitions allowed during recombination events, which is a function of the particular organic material selected as the emissive layer. Furthermore, current through the emissive layer is controlled by the voltage(s) applied to the drive transistor, which adjusts the conductivity of the drive transistor's channel region to control the current levels through the emissive layers (and the light emission).

[0004] Color displays are created by arranging a display with roughly a third of pixels emitting red light, a third emitting green light, and a third emitting blue light, with each group of three pixels forming an RGB pixel group composed of three sub-pixels that are independently programmed. Color content is displayed by programming each RGB pixel group to emit light according to a desired color for each position created by adding the RGB content together. Providing RGB pixels can be achieved by using emissive layers that generate light in red, green, and blue, respectively and patterning the appropriate emissive layers in the emissive regions of desired pixel circuits to create a desired RGB pattern.

[0005] Manufacturing such displays thus requires precisely patterning the respective emissive layers such that the appropriate emissive material is positioned in the proper emission region for each pixel. Shadow masks formed of thin metal are employed to screen regions where the emissive material is not desired while the emissive material is deposited on the display through the shadow mask. A shadow mask thus has a pattern of holes corresponding to the emission regions of all the red pixels and is aligned such that the holes match with the red pixels and the red emissive material is deposited. The shadow mask can then be moved (or another shadow mask positioned) such that holes align with the green pixels, and the green emissive material is deposited, etc. At very high pixel resolution (i.e., small pixel size) the holes in the shadow mask must become very small and the accuracy of the procedure suffers from non-uniformities in the emissive layers and difficulties in accurately aligning small holes.

[0006] In other examples, color displays can be formed from white emissive layers that are filtered to allow particular colors to be transmitted. That is, emissive layers that generate white light (which is itself a combination of red, green, and blue) can be provided in the emissive layers of all pixels. Color filters are arranged on the display substrate associated with particular pixels such that red, green, and blue light are transmitted from the display according to a desired RGB pattern. Filtering each color wastes a lot of power as a lot of generated light energy is simply filtered out with only a fraction being transmitted to contribute to the displayed color content.

SUMMARY

[0007] Arrangements and layouts are disclosed herein for multi-color pixel groups suitable for being patterned across a color display at a high pixel density. Some arrangements include organic emissive layers emitting distinct colors each deposited across continuous regions of a display panel so as to include more than one pixel emissive region. Color filters are situated to partially block light from at least some of the emissive regions such that primary additive colors are transmitted from distinct subsets of pixels on the display panel. Some arrangements provide for emissive layers deposited in alternating parallel stripes along rows or columns of the display. Some arrangements provide for emissive layers to be oriented perpendicularly with respect to one another such that the emissive layers overlap in a stacked configuration in the emissive regions of at least some pixels. In some examples, red, green, and blue of pixels are arranged in regular patterns across the display and with the emissive regions for the blue pixels forming a relatively larger area of the display than either the red or green pixels.

[0008] Aspects of the present disclosure provide a high resolution display panel including a display substrate, first and second substantially continuous emissive organic layer, and one or more first color filters. The display substrate includes a plurality of driving circuits each including a drive transistor coupled to an electrode such that the substrate includes a plurality of electrodes each coupled to a respective drive transistor. The first substantially continuous emissive organic layer is deposited in a first area of the display panel including at least two of the plurality of electrodes. The first emissive organic layer is configured to emit light according to a first color spectrum responsive to current being conveyed through the first emissive organic layer. The second substantially continuous emissive organic layer is deposited in a second area of the display panel including at least two of the plurality of electrodes. The second emissive organic layer configured to emit light according to a second color spectrum responsive to current being conveyed through the second emissive organic layer. The first color filters are situated to partially block light emitted from at least one of the first or the second emissive organic layers such that light transmitted through the one or more first color filters is characterized by a color spectrum for a first fundamental color.

[0009] Aspects of the present disclosure provide a method of fabricating a high resolution display panel that includes a display substrate with a plurality of driving circuits conveying currents to a plurality of electrodes via drive transistors and an emission region receiving the currents from the plurality of electrodes. The method includes depositing first and second substantially continuous emissive organic layers, and situating one or more first color filters situated to partially block

light emitted from at least one of the first or the second emissive organic layers. The first substantially continuous emissive organic layer is deposited with a substantially constant thickness in a first area of the display panel including at least two of the plurality of electrodes. The first emissive organic layer is configured to emit light according to a first color spectrum responsive to current being conveyed through the first emissive organic layer. The second substantially continuous emissive organic layer is deposited with a substantially constant thickness in a second area of the display panel including at least two of the plurality of electrodes. The second emissive organic layer is configured to emit light according to a second color spectrum responsive to current being conveyed through the second emissive organic layer. The one or more one or more first color filters are situated to such that light transmitted through the one or more first color filters is characterized by a color spectrum for a first fundamental color.

[0010] Aspects of the present disclosure provide a high resolution display system including a display substrate, a first multi-color pixel group situated on the display substrate, and a controller. The first multi-color pixel group includes a first pixel circuit, a second pixel circuit, a first substantially continuous emissive layer, and a first color filter. The first pixel circuit includes a first emission region and a driving circuit having a drive transistor and a storage capacitor configured to convey current through the emission region via the drive transistor according to a charge on the storage capacitor. The second pixel circuit includes a second emission region and a driving circuit having a drive transistor and a storage capacitor configured to convey current through the emission region via the drive transistor according to a charge on the storage capacitor. The first substantially continuous emissive layer is deposited with a substantially constant thickness in a first area including the first emission region and the second emission region. The first emissive layer is configured to emit light according to a first color spectrum responsive to current being conveyed through the first emissive layer. The first color filter is situated to partially block light emitted from the first emission region such that light of a first fundamental color is transmitted through the first color filter. The controller is configured to program the driving circuits of the first and second pixel circuits according to programming information during a programming cycle such that the pixel circuits emit light according to the programming information during a driving cycle following the programming cycle.

[0011] The foregoing and additional aspects and embodiments of the present invention will be apparent to those of ordinary skill in the art in view of the detailed description of various embodiments and/or aspects, which is made with reference to the drawings, a brief description of which is provided next.

BRIEF DESCRIPTION OF THE DRAWINGS

[0012] The foregoing and other advantages of the invention will become apparent upon reading the following detailed description and upon reference to the drawings.

[0013] FIG. 1A is an exploded diagram of a display panel with a TFT backplane having an array of electrodes for driving current through one or more organic emissive layers and a pattern of color filters to partially block light from the emissive layers.

[0014] FIG. 1B is a circuit diagram of a representative driving circuit in the TFT backplane for a pixel in an active

matrix display including a storage capacitor and a drive transistor for conveying current through the emission region according to charge on the storage capacitor.

[0015] FIG. 1C is a side view of an emissive region for a single pixel including stacked emissive layers and a color filter.

[0016] FIG. 2A is a top view of a layout for an RGBW multi-color pixel group formed with a substantially continuous strip of blue emissive material on the blue and white terminals.

[0017] FIG. 2B is an aspect view of the RGBW multi-color pixel group layout with the strip of blue emissive material formed over a layer of orange emissive material.

[0018] FIG. 2C is an aspect view of the RGBW multi-color pixel group layout with the layer of orange emissive material formed over the strip of blue emissive material.

[0019] FIG. 2D is a top view of an alternative configuration of the RGBW multi-color pixel group with the red and green sub-pixels having elongated emissive regions.

[0020] FIG. 2E is a top view of a layout for an RGB multi-color pixel group including emissive layers arranged similarly to the layouts of FIGS. 2A and 2D.

[0021] FIG. 3A is a top view of a layout for an RGB multi-color pixel group formed from alternating strips of orange and blue emissive material and with a blue sub-pixel enlarged relative to red and green sub-pixels.

[0022] FIG. 3B is a top view of a layout for an RGB multi-color pixel group similar to the layout in FIG. 3A, but where the red and green sub-pixels have elongated emissive regions.

[0023] FIG. 4A is another top view of a layout for RGB multi-color pixel groups formed from alternating strips of orange and blue emissive materials and with adjacent blue subpixels being associated with red and green sub-pixels in alternating upper and lower rows.

[0024] FIG. 4B is a top view of a layout for an RGB multi-color pixel group similar to the layout of FIG. 4A, but where the blue subpixels in each RGB multi-color pixel group have a larger area than either the red or green subpixels.

[0025] FIG. 4C is a top view of a layout for an RGB multi-color pixel group similar to the layout of FIG. 4B but where adjacent multi-color pixel groups share a common unitary blue subpixel.

[0026] FIG. 4D is a top view of a layout for an RGB multi-color pixel group similar to the layout of FIG. 4B with the red and green sub-pixels having elongated emissive regions.

[0027] FIG. 5 is a top view of a layout for an RGB multi-color pixel group formed from parallel strips of red and green emissive materials overlapped with perpendicularly aligned strips of blue emissive material.

[0028] FIG. 6A is a top view of a layout for RGB multi-color pixel groups formed from parallel strips of red and green emissive materials overlapped with perpendicularly aligned strips of blue emissive material with blue sub-pixels enlarged relative to red and green sub-pixels.

[0029] FIG. 6B is an aspect view of the RGB multi-color pixel groups of FIG. 6A showing alignment of the layers of emissive material and color filters with respect to a TFT backplane.

[0030] While the invention is susceptible to various modifications and alternative forms, specific embodiments have been shown by way of example in the drawings and will be described in detail herein. It should be understood, however, that the invention is not intended to be limited to the particular forms disclosed. Rather, the invention is to cover all modifi-

cations, equivalents, and alternatives falling within the spirit and scope of the invention as defined by the appended claims.

DETAILED DESCRIPTION

[0031] FIG. 1A is an exploded diagram of a display panel 10 with a TFT backplane 20 having an array of electrodes for driving current through one or more organic emissive layers 40 and a pattern of color filters 60 to partially block light 50 from the emissive layers 40. The TFT backplane 20 can be formed on a substrate and include an array of pixel circuits for receiving programming information and conveying driving currents 30 through the emissive layers 40. Generally, the TFT backplane 20 includes an array of electrodes (e.g., the electrodes 22*r*, 22*g*, 22*b*, etc.) arranged in rows and columns with each electrode being associated with a distinct pixel circuit for driving current through the emissive layers 40 via its respective electrode.

[0032] Generally, the TFT backplane is an active matrix backplane and each pixel circuit in the TFT backplane includes a drive transistor and a storage capacitor. The drive transistor is generally in series with its respective electrode such that currents driven through the drive transistor are also conveyed through the corresponding portions of the emissive layers 40, via its respective electrode. The storage capacitor is generally situated to influence the conductance of the drive transistor such that the current conveyed through the drive transistor is controlled by the charge on the storage capacitor. The charge on the storage capacitor can be set (i.e., programmed) according to programming information conveyed to the pixel circuit via a data line driven by a data driver according to display information, such as, for example a digital video stream. Thus, in some embodiments, each pixel circuit can be programmed according to display information during a programming cycle, which charges the storage capacitor via voltage programming, current programming, or a combination thereof, and then driven to emit light according to the programming information during an emission cycle following the programming cycle. In some embodiments, the duration of the programming cycle corresponds to an interval during which the pixel circuit is connected to a data line.

[0033] An exemplary pixel circuit 100 is provided in FIG. 1B, which is discussed further below. In an example implementation, the pixel circuits in the TFT backplane 20 can be configured different from the pixel circuit 100 shown in FIG. 1B. The TFT backplane 20 can include connections to a data driver 132 and an address driver 134 to program and drive the pixel circuit 100 to convey the driving currents 30 to the emission layers 40 and thereby cause emitted light 50 to be transmitted through the color filter layer 60 such that the filtered light 70 is transmitted outward from the display system 10. As shown in the exemplary pixel circuit 100 of FIG. 1B, a controller 130 receives display data 138 and sends command signals to the address driver 134 and the data driver 132 cause the pixel circuit 100 to be programmed and driven according to the received display data 138. The controller 130 can also adjust (“tune”) the programming and/or driving according to information stored in an associated memory 136. For example, the memory 136 can include a lookup table to provide adjustment values for one or more pixel circuits in the display panel including the pixel circuit 100 to scale or otherwise adjust programming values to account for degradation (e.g., aging) of the electrical components within the pixel circuit 100. For example, the programming values can be adjusted to account for changes in threshold voltage of the

driving transistor, changes in the turn on voltage of the light emitting device, and/or changes in the current-voltage characteristics of the driving transistor. Additionally or alternatively, the memory 136 can store coefficients for formulas (or lookup tables) characterizing an amount of adjustment for each pixel circuit (or subsets thereof) based on the programming value provided, the operation history of the pixel circuit, one or more measurements of the pixel circuit (e.g., current values, light emission values, etc.), and/or the age (“operating hours”) of the display.

[0034] Generally, the TFT backplane 20 includes a plurality of distinct pixel circuits that can each be programmed according to programming information and driven to provide a driving current through an emissive region according to the programming information. The driving currents can be conveyed via distinct driving terminals associated with each pixel circuit. By programming the full panel of such pixel circuits, the display panel 10 can be driven to display an image, and dynamically updating the displayed content at a sufficiently high refresh rate causes the display panel 10 to display video content. Furthermore, the display panel 10 can display color content by situating pixels that emit particular colors across the display panel. For example, the display panel 10 can be arranged with a regularly repeating pattern of red, green, and blue pixels such that a light can be generated from the display panel according to a programmable combination of red, green, and blue light. Additionally or alternatively, the display panel 10 can also be arranged with pixels emitting white light, cyan light, magenta light, yellow light, orange light, etc. The exemplary arrangement of color-specific pixels shown in FIG. 1A is described next in detail.

[0035] The TFT backplane 20 includes a first pixel group 22 and a second pixel group 24. Both the first pixel group 22 and the second pixel group 24 include three distinct pixel circuits each having a distinct terminal. The first pixel group 22 includes a red terminal 22*r*, a green terminal 22*g*, and a blue terminal 22*b*. The second pixel group 24 also includes a red terminal 24*r*, a green terminal 24*g*, and a blue terminal 24*b*. Driving currents 30 are conveyed via the respective terminals 22*r,g,b*, 24*r,g,b*, etc. to the emissive layer 40. The emissive layer 40 is arranged with alternating elongated strips of substantially continuous blue emissive material 41, 48 and orange emissive material 45. Certain organic materials have molecular structures that provide an energy gap between the highest occupied molecular orbital and the lowest unoccupied molecular orbital, and by injecting holes and free electrons to the organic material, luminescent recombination events occur to emit light with characteristic energies near the energy gap. Accordingly, particular organic materials can be selected with electroluminescence spectra of varying colors, such as materials emitting blue light, orange light, red light, etc. to generate the emitted light 50 with desired color characteristics. In the display panel 10 shown in FIG. 1A, the strips of blue emissive material 41, 48 emit blue light while the strip of orange emissive material 45 emits orange light.

[0036] The first strip of blue emissive material 41 is situated to overlap (“coat”) the blue terminals 22*b*, 24*b* from the first and second pixel groups 22, 24. The first strip of blue emissive material 41 can be developed over the blue terminals 22*b*, 24*b* by a deposition process using a thin shadow mask with an elongated slit opening situated over an area including the blue terminals 22*b*, 24*b*. Similarly, the strip of orange emissive material 45 is situated to overlap (“coat”) the red and green terminals 22*r,g* and 24*r,g* from the first and second pixel

groups 22, 24, and can be developed by a deposition processing using a thin shadow mask having an elongated slit opening. Thus, the strips of emissive material 41, 45 generally each extend continuously over an area of the display panel that includes more than one terminal of the TFT backplane 20. However, as previously described the emissivity of the emissive strips 41, 45 (i.e., the luminance emitted light 50) is regulated by the amount of current flowing through the materials (and thus the amount of light-emitting recombination events occurring within the materials).

[0037] The driving currents 30 flow through the emissive layers 40 primarily vertically through the material along the shortest path between the terminals of the TFT backplane and corresponding terminals on the opposite side of the emissive layer 40, which may be, for example, transparent conductive terminals of indium tin oxide (ITO) or a similar material providing a supply line voltage (e.g., V_{dd} or V_{ss}). In particular, the emissive layers 40 are relatively resistive to current flowing horizontally along the layers 40, rather than through the layers 40, thus the driving currents 30 from each terminal in the TFT backplane 20 generally flow through the layers 40 only in confined regions situated over each terminal. In other words, the strips of emissive material 41, 45, 48 can be considered as an array of separately programmed emissive regions for each pixel circuit, even though the strips 41, 45, 48 are arranged as continuous layers spanning multiple pixels. In the exemplary configuration of the display panel 10, the first strip of emissive blue material 41 includes a first area 42 and a second area 43 each situated over a distinct terminal in the TFT backplane 20. The first area 42 is situated to overlap the blue terminal 22b in the first pixel group 22 and emit blue light according to the driving current 30 from the blue terminal 22b. The second area 43 is similarly situated to overlap the blue terminal 24b in the second pixel group 24 and emit blue light according to the driving current 30 from the blue terminal 24b.

[0038] Similarly, the strip of emissive orange material 45 includes multiple discrete areas corresponding to the distinct terminals of the TFT backplane 20, where each area in the orange strip 45 luminesces according to the driving currents 30 from each terminal. By way of example, the strip of orange emissive material 45 includes a first area 46 situated to emit orange light according to a driving current 30 conveyed from the green terminal 22g and also a second area 47 situated to emit orange light according to a driving current 30 conveyed from the red terminal 22r. The patterned color filters 60 are arranged over the strip of orange emissive material 45 to selectively transmit the red components (70) and green components (70) of the emitted orange light 50. A green filter 62 is arranged over the first area 46 and a red filter is arranged over the second area 47. Similarly, a green filter 66 and a red filter 68 are arranged over the orange emissive layer 45 at regions corresponding to the green terminal 24g and the red terminal 24r, respectively, for the second pixel group 24. The red filters 62, 66 selectively transmit the red color content from the electroluminescence spectrum of the orange emissive material 45 while the green filters 64, 68 selectively transmit the green color content from the electroluminescence spectrum of the orange emissive material 45. In some examples, the red and green filters can be applied by a lithographic process.

[0039] The display panel 10 provides one exemplary arrangement for constructing a high resolution color display. For example, because the organic emissive materials can be

deposited as substantially continuous elongated strips that span multiple pixel circuits, the dimensions of the individual emissive regions/areas (e.g., the areas 46, 47, etc.) are not subject to several problems associated with other color displays. According to some other techniques, shadow masks made of thin metal (e.g., approximate thickness of 10 μm) with openings/holes arranged in a pattern for each color are placed over a display substrate before depositing color-specific emissive materials. For example, a shadow mask with openings at the positions of the red pixels is positioned over a display substrate with the openings aligned with the red pixels and a red emissive material was deposited; next a shadow mask with openings at the positions of the blue pixels is positioned over the display substrate and a blue emissive material was deposited, and so on for additional colors. These techniques suffers from difficulty in aligning the shadow masks with precision in two dimensions (along both height and width of the display panel), and also introduce practical limits on the minimum dimensions of the distinct emissive regions created via such shadow masks.

[0040] At very high display resolutions, with pixel resolutions approaching (or even exceeding) 300 pixels per inch (ppi), the pixel pitch (i.e., size of the active region for each pixel) is necessarily small, with typical dimensions of each emissive region on the order of 10-20 micrometers, which is also the approximate thickness of the shadow mask itself. In such instances, directional deposition processes suffer from a shadowing problem resulting in non-uniform thickness of the deposited organic film across the emissive region, even where the shadow mask is in direct contact with the display substrate. The non-uniform thickness results from the angle between the direction deposition source and the emissive region, resulting in some portion of the emissive region lacking a line-of-sight to the deposition source, due to an edge of the mask casting a "shadow" blocking a portion of the emissive region from the deposition source. The shadowed portion of the emissive region receives relatively little organic material in comparison to the non-shadowed portions of the emissive region. When the dimensions of the emissive region (i.e., the dimension of the openings in the shadow mask) are significantly larger than the dimensions of the thickness of the mask itself, this "shadowing" effect can largely be ignored. However, as the dimensions of the shadow mask approach the thickness of the shadow mask, the "shadowing" problem is exacerbated and can even result in an absence of organic emissive material in a portion of the emissive region.

[0041] Some aspects of the present disclosure allow for a shadow mask to be formed with elongated openings that correspond to an area of the TFT backplane 20 spanning more than one terminal. The elongated openings are less susceptible to shadowing effects because the boundaries of the resulting emissive regions are defined by edges of the shadow mask in one direction, rather than in both directions. In addition, the shadow masks can be generally arranged to be carefully aligned along one direction, with a greater alignment tolerance along the orientation of the elongated openings to facilitate rapid construction and assembly of such displays.

[0042] Furthermore, aspects of the present disclosure provide for situating color filters (e.g., the color filters 70) over one or more emissive layers (e.g., the orange emissive material 45) to selectively transmit light from the emissive material according to its color content. Advantageously, the present disclosure provides for displays that include color filters over only a portion ("sub-set") of the total pixels such

that light generated in the sub-set is partially blocked (via the filters), while light generated by other pixels is not filtered. Using color filters to create color content is a wasteful energy-consuming process, because the emissive regions are required to generate light that does not contribute to the display content (i.e., the light that is filtered/absorbed in the color filters represents energy that does not contribute to the display content).

[0043] Thus, in contrast to a display that generates white light in the emissive regions for each pixel and then situates appropriate color filters over every pixel to selectively transmit light with the desired color content, the arrangement in FIG. 1A (and other arrangements discussed herein) allow for selective filtering of a subset of the pixels while other pixels emit light without being filtered. Such arrangements increase the energy efficiency and/or operating lifetime of such a device by decreasing the amount of light that is inefficiently produced (and absorbed in filters). In particular, the operating lifetimes of the emissive regions and/or the circuit elements in the TFT backplane can be extended by the present display arrangements by decreasing the amount of electrical stress on the semi-conductive components. Lowering the light production from each pixel decreases such stresses by decreasing current density through the emissive layers and the magnitude of the driving currents 30, and hence decreasing the voltage stresses on the respective driving transistors.

[0044] Some embodiments of the present disclosure further provide for multi-color pixel groups formed to include a larger emissive region for blue light emission than for other colors. Blue emissive materials are more sensitive to electrical degradation and typically degrade at a higher rate than emissive materials for other colors. In some instances, the lifetimes of display devices due to electrical degradation of the emissive materials are controlled predominantly by the aging of the blue emissive materials which emit less light and/or require higher operating voltages over their lifetime to achieve a steady luminance. However, the aging of blue emissive materials can be reduced by decreasing the current density through the emissive material. Thus, a tradeoff may be made between display brightness (or emissivity, which correlates with current density) and display aging, which occurs more rapidly at higher current densities. However, by increasing the relative area of the blue emissive region(s), the current density through the blue emissive material can be decreased while achieving substantially the same light output from the blue material. In other words, a large blue emissive region allows the total current through the blue emissive material (and thus the total emissivity) to be the same as for a small blue emissive region, but the current density (which determines aging degradation) through the large region can be less than for the small region. For example, a multi-color pixel group can include red, green, and blue sub-pixels and the blue sub-pixel can include an emission region roughly twice the size of the emission regions for each of the red and green sub-pixels. In such an arrangement, the current density through the blue sub-pixel is approximately half the value it would otherwise be if the blue emission region was the same size as the red and green emission regions. As a result, the total aging degradation of such a display is generally less than displays with equal sized emissive regions for each color, because the aging is not dominated by the degradation of the blue material.

[0045] FIG. 1B is a circuit diagram of a representative pixel circuit 100 in the TFT backplane 20 for a pixel in an active

matrix display including a storage capacitor 116 and a drive transistor 112 for conveying current through the emission region according to charge on the storage capacitor 116. The pixel circuit 100 is connected to a data line 122, a select line 120, and first and second power supply lines 124, 126. A controller 130 receives display data 138 (such as a video stream, etc.) indicating an amount of luminance to be emitted from the pixel circuit 100. The controller 130 operates a data driver 132 and an address driver 134 to program the pixel circuit 100 according to the received display data 138 during a programming cycle, and allow the pixel circuit 100 to emit light during an emission cycle. During the programming cycle for the pixel circuit 100, the address driver 134 sets the select line 120 to turn on the switch transistor 118 such that the data line 122 is connected to the storage capacitor 116 via the switch transistor 118. Programming information is conveyed to the pixel circuit 100 to charge the storage capacitor 116 via the data line 122. The storage capacitor 116 is desirably arranged such that the drive transistor 112 is driven during the emission cycle according to a charge developed on the storage capacitor 116 during the programming cycle. As shown in FIG. 1B, the storage capacitor 116 can be connected between a gate terminal of the drive transistor 112 and a stable voltage, such as a ground voltage, reference voltage, etc., sufficient to allow the storage capacitor 116 to be charged according to the programming voltage. In some examples, the storage capacitor can be connected between the gate and/or source terminals of the drive transistor 112 such that the charge established on the storage capacitor 116 influences the conductance of the channel region of the drive transistor 112. Thus, setting charging the voltage on the storage capacitor 116 thereby controls the current conveyed through the drive transistor 112 (and through the OLED 114) according to the current-voltage characteristics of the drive transistor 112.

[0046] To initiate programming in the pixel circuit 100, the address driver 134 operates a select line 120 to turn on a switch transistor 118. For example, the address driver 134 can set the select line 120 high to turn on the switch transistor 118 and thereby connect the pixel circuit to the data line 122. The data line 122 is set to an appropriate programming voltage based on the display data 138 via the data driver 132. The programming voltage can optionally be adjusted to account for aging degradation according to information in the memory 136. The programming voltage on the data line 122 is conveyed, via the switch transistor 118, to a storage capacitor 116 which is connected to the gate of a drive transistor 112. The storage capacitor 116 is connected to a ground voltage at a terminal opposite the one connected to the gate of the drive transistor 112, to thereby situate the storage capacitor to be charged according to the difference between the programming voltage and the ground voltage. However, it is specifically noted that the storage capacitor 116 can also be connected to another stable voltage suitable for allowing the storage capacitor 116 to be charged according to the programming voltage, such as, for example, a power supply voltage line (e.g., Vdd or Vss), a terminal of an OLED, or another terminal sufficient to prevent the storage capacitor 116 from floating during programming. The drive transistor 112 is connected in series with a light emitting device 114, which can be an OLED, for example. The drive transistor 112 and light emitting device 114 series is connected between first and second power supply lines Vdd 124 and Vss 126. The power supply lines Vdd 124 and Vss 126 can provide fixed voltages or can optionally be dynamically adjusted. For example, one

or both of the power supply lines **124**, **126** can be adjusted to a value sufficient to reverse bias the light emitting device **114** during a programming cycle to thereby prevent emission from the light emitting device **114** during the programming cycle while the light emitting device **114** is being programmed.

[0047] Thus, the pixel circuit **100** can be operated to emit light according to programming information by turning on the switch transistor **118**, via the address driver **134**, while a suitable programming voltage is established on the storage capacitor **116**, via the data driver **132**. The switch transistor **118** is then turned off and the voltage on the storage capacitor **116** controls gate-source voltage of the drive transistor by setting the voltage on the gate of the drive transistor **112**. Because the conductance of the channel region of the drive transistor **112** is influenced by its gate-source voltage (e.g., according to the current-voltage characteristics of the drive transistor **112**), the current level through the drive transistor **112** is determined by the charge on the storage capacitor **116**. Furthermore, because the emissivity of the light emitting device **114** is established by the current flowing through the light emitting device **114**, the light output from the pixel circuit **100** is controlled according to the voltage on the storage capacitor **116** during the driving cycle.

[0048] In some examples, the data driver **132** can set the data line **122** to a programming voltage, which allows the storage capacitor **116** to be charged according to the programming voltage. In other examples, the data line **122** can optionally convey programming currents and the pixel circuit **100** can be arranged to allow the storage capacitor **116** to be charged according to a voltage sufficient to maintain the programming current (or a current related to the programming current) through the drive transistor **112** or another transistor such as a mirror transistor.

[0049] In some pixel architectures disclosed herein, the pixel circuits can include a stacked ("layered") region forming one or more OLEDs and including more than one distinct emissive layer emitting light according to the current passing through each layer (such as in FIGS. 2A-2E). FIG. 1C is a side view of an exemplary emissive region for a single pixel including stacked emissive layers and a color filter provided for illustrative purposes. The stacked region shown in FIG. 1C can be considered two OLEDs **171**, **172** connected in series between a driving electrode **142** and a power supply line **166**. The power supply line **166** can be a transparent conductive material such as indium tin oxide (ITO) arranged on or near the encapsulation substrate **170**. Each OLED **171**, **172** includes a cathode (the electron injection layers **144**, **156** (EILs)) and an anode (the hole transport layer **152** and hole injection layer **164**).

[0050] The driving electrode **142** is situated on a TFT backplane **140**. The driving electrode **142** can be similar to the electrodes ("terminals") of the TFT backplane **20** in FIG. 1A (e.g., the terminals **22r,g,b** of the first pixel group). The driving electrode **142** is connected in series with a driving transistor for a pixel circuit within the TFT backplane such that current conveyed via the driving electrode **142** is controlled by the pixel circuit. For example, with reference to the pixel circuit **100** of FIG. 1B, the driving electrode **142** can be connected to the drain terminal of the driving transistor **112**. Referring again to FIG. 1C, the electron injection layer (EIL) **144** is situated on the driving electrode **142**. The EIL **144** can generally be formed from a material including a conductive metal with a relatively high work function suitable for pro-

viding free electrons to the OLEDs **171**, **172**, such as, for example, aluminum, gold, etc. The EIL **144** can also be a reflective material such that light emitted from one or both of the OLEDs **171**, **172** is redirected toward the cap glass **170**. The EIL **144** can also be considered the cathode terminal of the OLED, and in some embodiments can be integrated with or otherwise combined with the driving electrode **142**.

[0051] The first OLED **171** includes the EIL **144**, a hole blocking layer **146** (HBL), a first emissive layer **148** (El-1), an electron blocking layer **150** (EBL), and a hole transport layer **152** (HTL). The HBL **146** is situated over the EIL **144** to prevent positively charged holes from reaching the EIL, where the holes would recombine with electrons outside of the first emissive layer **148** (El-1). The El-1 **148** is an organic film with a molecular structure suitable for emitting light **149** with a first color in response to hole-electron recombination events occurring within El-1 **148**. The HBL **146** thus increases the efficiency of the first OLED **171** by maximizing the number of recombination events (and thus emission events) that occur within El-1 **148**. The EBL similarly increases the efficiency of the first OLED **171** by blocking free electrons from traveling to the HTL **152**, to thereby prevent the occurrence of inefficient (i.e., non-light generating) recombination events outside the emissive layer **148**.

[0052] One or more intermediate layers **154** are provided between the HTL **152** (which is also the anode of the first OLED **171**) and the EIL **156** (which is also the cathode of the second OLED **172**). The intermediate layers **154** can include substantially transparent and/or semi-transparent materials suitable for conveying positive charged holes traveling from the second OLED **172** to the HTL **152** of the first OLED **171**. In some instances, the intermediate layers **154** can include tungsten trioxide, other nitrides and/or oxides, conductive metals, etc.

[0053] The second OLED **172** includes the EIL **156**, an electron transport layer **158** (ETL), a second emissive layer **160** (El-2) a hole transport layer **162** (HTL), and the HIL **164**. The EIL **156** and HIL **164** define the cathode and anode of the second OLED **172**, respectively. The EIL **156** is situated on the intermediate layers **154** and releases free electrons through the ETL **158** toward the emissive layer **160**. In some examples, the EIL **156** and the ETL **158** can be combined in a single layer. The El-2 **160** is another organic film with a molecular structure suitable for emitting light **161** with a second color in response to hole-electron recombination events occurring within the El-2 **160**. The HTL **162** and the HIL **164** are situated on the El-2 **160** for conveying positively charged holes to the El-2 **160**.

[0054] Thus, current flowing through the OLEDs **171**, **172** results in the generation of the first light **149** in the first emissive layer **148** (El-1), and the second light **161** from the second emissive layer **160** (El-2). The generated light **149**, **161** is conveyed through the transparent and/or semi-transparent layers, including the power supply line **166** formed of ITO toward the encapsulation glass **170**. A color filter **168** is included on one side of the encapsulation glass **170** to allow the generated light **149**, **161** to be selectively transmitted according to its color content. For example, the transmission spectrum of the color filter **168** can be such that the transmitted light is substantially red light, green light, or blue light. In one example, the light **149** emitted from El-1 **148** can be blue light while the light **161** emitted from the El-2 **160** can be orange light such that the combined light **149**, **161** jointly includes a significant portion of the visible color spectrum

and can be considered white light. Thus, the color filter **168** can selectively transmit particular color contributions to the white light (e.g., red, green, blue color contributions). In another example, the light **149** emitted from EI-1 **148** can be red light while the light **161** emitted from the EI-2 **160** can be blue light and the color filter **168** can be red or blue so as to selectively transmit light from one of the emissive layers (e.g., EI-1 **148** or EI-2 **160**) while largely blocking (“absorbing”) light from the other one.

[0055] The exemplary emissive region shown in FIG. **1C** refers to a pixel circuit arranged to be “top-driven” with current flowing from the power supply line **166**, through the OLEDs **171**, **172** toward the driving electrode **142** which regulates the current level according to a series-connected driving transistor within the backplane **140**. However, aspects of the present disclosure apply to bottom-driven pixel circuits arranged with a driving transistor connected in series with an anode of a layered OLED device, and current flows from the driving electrode, through the OLED, and toward another power supply line. In bottom-driven pixel arrangements, it is also contemplated that the color filters (e.g., the color filters **60** in FIG. **1A**) can be applied to the display substrate (e.g., via a lithographic process).

[0056] In the following figures and accompanying descriptions, several examples of arrangements (“architectures”) for arranging a multi-color pixel group with emissive layers that span multiple terminals and with color filters arranged to filter light from a subset of the pixels in each arrangement. It is specifically contemplated that the pixel groups disclosed herein can be patterned across a display panel and arranged in rows and columns to allow for independently controlled color content across a display panel to thereby generate color images and/or video. In addition, it is specifically noted that the arrangements and architectures described herein include layouts for emissive regions, driving terminals, and/or color filters, and can be applied to a variety of pixel circuits employing a variety of different programming and driving schemes. In addition, it is specifically understood that additional layers and/or materials can be included between and/or around emissive layers, such as described by way of example in FIG. **1C**.

[0057] Furthermore, for clarity and consistency of the present disclosure, the arrangements and architectures included herein are described as top-driven pixel circuits situated on a TFT backplane substrate including a pattern of separately controllable driving terminals. However, it is noted that the present disclosure applied to other pixel circuit layouts including bottom-driven arrangements.

[0058] FIG. **2A** is a top view of a layout **200** for an RGBW multi-color pixel group formed with a substantially continuous strip of blue emissive material **220** on a blue driving terminal **206** and a white driving terminal **208**. The RGBW pixel group includes a red pixel **R1** defined by the red driving terminal **202**, a green pixel **G1** defined by a green driving terminal **204**, and blue and white pixels (**B1** and **W1**) defined by a blue driving terminal **206** and a white driving terminal **208**, respectively. An orange emissive material **222** is distributed in a layer covering all the terminals in the RGBW group. Thus, orange light is produced from the emissive regions for the red and green pixels (**R1** and **G1**) via the orange emissive layer **222**. A red filter **212** is situated over **R1** to selectively transmit the red content in the emitted orange light, while a green color filter **214** is situated over **G1** to selectively transmit the green content in the emitted orange light. A blue filter

216 is situated over **B1** to selectively transmit the blue light (emitted via the blue emissive strip **220**) while blocking light from the orange layer **222**. The white pixel emits substantially all the substantially white light from the combined stack of orange light (via the orange layer **222**) and blue light (from the blue layer **220**).

[0059] In some embodiments of the layout **200**, the red, green, blue, and white pixels of the RGBW pixel group each include emissive regions with a similar size and/or area. Generally, the size and/or shape of the emissive region of the pixels in the layout **200** are defined by the size of the corresponding driving terminals (e.g., the driving terminals **202**, **204**, **206**, **208**). In some cases the driving terminals **202-208** can each be approximately the same size. For example, the RGBW pixel group can be arranged as a square divided in quadrants and each quadrant can include one of the driving terminals **202-208**. Furthermore, each of the driving terminals **202-208** can be a square or rounded square with similar heights and widths, and the color filters **212-216** can be arranged with similar dimensions to the driving terminals **202-206** so as to filter light from the respective emissive regions of the pixels **R1**, **G1**, **B1**.

[0060] FIG. **2B** is an aspect view of the RGBW multi-color pixel group layout **200** with the strip of blue emissive material **220** formed over a layer of orange emissive material **222**. In some embodiments, a display panel formed with pattern of pixels arranged according to the layout **200** can be formed by depositing (“developing”) the orange emissive layer **222** in a substantially uniform, continuous layer across the display panel. Following the development of the orange layer **222**, any desired intermediate layers can be situated, and a shadow mask can be aligned with an elongated opening over the blue and white pixels **B1**, **W1**. For example, the elongated opening can extend across multiple such pixel groups in a continuous line of adjacent alternating blue and white pixels in multiple RGBW pixel groups. The blue emissive layer **220** can be deposited in the desired region while the shadow mask blocks the blue emissive material from the red and green pixels **R1**, **G1**. Additional layers and/or conductive power supply lines can be arranged on the emissive regions of the display panel and the color filters can then be arranged such that the desired colors are transmitted from each of the red, green, blue, and white pixels in each group. As previously noted, a lithographic process can be employed to apply appropriate color-selective filtering materials (e.g., the color filters **212**, **214**, **216**) to the display substrate and/or encapsulation substrate.

[0061] FIG. **2C** is an aspect view of the RGBW multi-color pixel group layout **200** with the layer of orange emissive material **222** formed over the strip of blue emissive material **220**. In an exemplary process to construct a display panel with RGBW pixel group layout **200**, a shadow mask is situated with an elongated opening over blue and white terminals for multiple pixels and the blue emissive material **220** is deposited in a substantially continuous layer in the region defined by the shadow mask opening. Intermediate layers are situated as desired and the entire display panel is coated with a substantially continuous layer of the orange emissive material **222**. The color filters **212**, **214**, **216** are arranged over the red, green, and blue pixels (**R1**, **G1**, **B1**) to selectively transmit red, green, and blue light. Thus, the layout **200** of FIG. **2A** can be achieved without regard to the order of the orange and blue emissive materials **222**, **220** in the stacked emissive regions of the blue pixel **B1** and white pixel **W1**.

[0062] FIG. 2D is a top view of an alternative configuration of the RGBW multi-color pixel group layout **240** with a red pixel **R2** and a green pixel **G2** each having elongated emissive regions. The emissive materials **220**, **222** in the RGBW pixel group **240** are arranged similarly to the emissive layers in the RGBW pixel group **200** in FIGS. 2A-2C, with the orange emissive material **222** distributed in a substantially continuous layer across all pixels in the group, and a strip of blue emissive material **220** over the blue terminal **206** and the white terminal **208**. Thus, the blue pixel **B2** and the white pixel **W2** are arranged similarly to the pixels **B1** and **W1** in the pixel group layout **200**. However, the arrangement of the red driving terminal **232** and the green driving terminal **234** differs from the RGBW pixel group layout **200**. As shown in FIG. 2D, the RGBW pixel group layout **240** is arranged roughly as a square with approximately equal width and height. The driving terminals for the red and green pixels **232**, **234** are each arranged as rectangles with a length spanning (or nearly spanning) the height dimension of the RGBW pixel group **240**. The width of the terminals **232**, **234** is approximately one quarter the width of the RGBW pixel group layout **240**. In some embodiments, the elongated driving terminals **232**, **234** can have approximately the same surface area as the terminals **202**, **204** arranged approximately as squares in quadrants of the square-shaped multi-color pixel group layout **200**.

[0063] A red color filter **242** is situated to selectively transmit the red light from the orange emissive layer **222** receiving current from the red driving terminal **232**. Similarly, a green color filter **244** is situated to selectively transmit the green light from the orange emissive layer **222** receiving current from the green driving terminal **232**. The dimensions, size, and/or shape of the color filters **242**, **244** can be selected to correspond to the dimensions, size, and/or shape of the respective driving terminals **232**, **234**. In some examples, the color filters **242**, **244** can be larger than their corresponding driving terminals **232**, **234** to allow the color filters **242**, **244** to completely overlap the emissive regions of the pixels **R2**, **G2**, while allowing for some alignment tolerance in positioning the color filters **242**, **244** with respect to the pixels **R2**, **G2** (and their respective driving terminals **232**, **234**).

[0064] While the present disclosure includes two specific arrangements for the red and green pixels with **R1**, **G1** approximately arranged as squares in quadrants of the layout **200** (FIG. 2A) and **R2**, **G2** approximately arranged as adjacent rectangles extending the length of the pixel group layout **240** (FIG. 2D), the present disclosure extends to other arrangements. Generally, the driving terminals for the red and green pixels can be arranged to divide a portion of a multi-color pixel group that includes a layer of orange emissive material into distinct areas that are separately programmed and driven to emit light. Red and green color filters are situated in regions corresponding to the driving terminals such that red light is selectively transmitted from one pixel and green light is selectively transmitted from the other pixel, and the shape of the color filters can be a shape that is based on the shape of the driving terminals. The red and green color filters are situated over the portions of the orange emissive material driven by the independently programmed driving terminals such that the transmitted light from each pixel circuit is substantially red and green, respectively.

[0065] FIG. 2E is a top view of a layout for an RGB multi-color pixel group layout **260** including emissive layers **220**, **222** arranged similarly to the layouts of FIGS. 2A and 2D.

The arrangement of the RGB pixel group **260** includes red, green, and blue pixels (**R3**, **G3**, and **B3**). The red pixel **R3** and green pixel **G3** pixels are arranged similarly to the red and green pixels **R1**, **G1** in the RGBW layout **200**, with the red and green pixels each arranged as a separately programmed quadrant of the square-shaped pixel group layout **260**. The blue pixel **B3** includes a blue driving terminal **266** that conveys current through the stacked emissive region including the strip of blue emissive material **220** and the orange emissive material **222**. A blue color filter **276** is situated to cover the blue pixel **B3** such that the light from the blue emissive material **220** is transmitted while the orange light from the orange emissive material **222** is blocked. Where a display panel is formed by patterning the layout **260** across a panel, adjacent blue pixels from multiple RGB pixel groups can be arranged in a continuous column (or row) of the panel, and the blue color filtering material can be applied to the strip of blue emissive material **220** across its entire length (or nearly entire length).

[0066] The blue driving terminal **266** spans roughly one-half of the square-shaped pixel group layout **260**. The blue pixel **B3** has a larger emissive region (as measured by area) than the emissive regions of either the red or green pixels **R3**, **G3**. Thus, blue light is emitted from approximately one-half of the pixel group, rather than approximately one-fourth, as in the pixel group layouts **200**, **240** of FIGS. 2A-2D. Furthermore, a display panel patterned according to the layout **260**, transmits blue light from roughly half (or nearly half) of the display area of the panel, similar to the display panel **10** of FIG. 1A. Similar to the discussion of the relative sizes of the blue pixel areas in connection with FIG. 1A, providing a layout (e.g., the layout **260**) with an increased relative size of the blue pixel allows for decreasing the current density through the strip of blue emissive material **220** without loss of display brightness and thereby allows for decreasing the aging degradation of the display panel.

[0067] FIG. 3A is a top view of a layout **300** for an RGB multi-color pixel group formed from alternating strips of orange emissive material **322** and blue emissive material **320** and with a blue sub-pixel **B4** enlarged relative to red and green sub-pixels (**R4**, **G4**). The red pixel **R4** includes a red driving terminal **302**; the green pixel **G4** includes a green driving terminal **304**; and the blue pixel **B4** includes a blue driving terminal **306**. The arrangement of the driving terminals **302-306** in the RGB pixel group **300** of FIG. 3A is similar to the driving terminal arrangement in the layout **260** of FIG. 3A. Generally, the RGB pixel group of FIG. 3A is arranged as a square with the red pixel **R4** and green pixel **G4** each occupying roughly one quadrant of the square, and the blue pixel **B4** occupying roughly the remaining half of the square. The strip of orange emissive material **322** is a substantially continuous layer that covers the driving terminals **312**, **314** of the red and green pixels (**R4**, **G4**). A red color filter **312** and a green color filter **314** are situated over the portions of the orange emissive material **322** driven by the red driving terminal **302** and the green driving terminal **304**, respectively. Thus, the RGB pixel group **300** transmits red light from the red pixel **R4**, green light from the green pixel **G4**, and unfiltered blue light is emitted from the blue pixel **B4**. As described previously, the relatively large size of the blue pixel **B4** in comparison to the red and green pixels (**R4**, **G4**) reduces degradation associated with the blue emissive material **320** by reducing the current density through the blue emissive mate-

rial. The layout **300** of the RGB pixel group in FIG. 3A is similar to the layouts of the multi-color pixel groups **22**, **24** of FIG. 1A.

[0068] FIG. 3B is a top view of a layout **340** for an RGB multi-color pixel group similar to the layout **300** in FIG. 3A, but where the red and green sub-pixels (R5, G5) have elongated emissive regions. The RGB pixel group is roughly arranged as a square, and the blue pixel B5 occupies roughly half of the square, similar to the blue pixel B4 in FIG. 3A. However, in the layout **340**, a red driving terminal **332** and a green driving terminal **334** are arranged as adjacent rectangles that jointly span roughly half of the square-shaped pixel group. The rectangular red and green driving terminals **332**, **334** can have lengths roughly spanning the height of the square-shaped pixel group, and with widths roughly spanning one-quarter the width of the square-shaped pixel group. A red color filter **342** and a green color filter **334** are situated over the portions of the orange emissive material **322** driven by the red driving terminal **332** and the green driving terminal **334**, respectively. In some examples, the layout **340** is preferred over the layout **300** of FIG. 3A, because the layout **340** situates all three pixels R5, G5, B5 of the multi-color pixel group in a single row, rather than splitting the red and green pixels across two rows (pixels R4, G4 of FIG. 3A). In some embodiments, arranging all the pixels R5, G5, B5 in a single row as in the layout **340** can allow for less redundancy and more uniform spacing in selection, addressing, programming, and/or power supply lines in the TFT backplane.

[0069] In comparison to the arrangements in FIGS. 2A-2E, the RGB pixel group layouts **300**, **340** of FIGS. 3A-3B do not include blue color filters, because the blue pixels B4, B5 include only blue emissive material and are not stacked emissive regions also including orange emissive material. Display panels formed by patterning either of the layouts **300**, **340** can thus be operated at a higher energy efficiency than the displays arranged according to the layouts **200**, **240**, **260** of FIGS. 2A-2E, because less light is filtered (i.e., wasted).

[0070] FIG. 4A is another top view of a layout **400** for RGB multi-color pixel groups formed from alternating strips of orange emissive material **420**, **424** and blue emissive material **422** and with adjacent blue pixels being associated with red and green sub-pixels in alternating upper and lower rows. Thus, a first RGB pixel group includes a red pixel R6, a green pixel G6, and a blue pixel B6. A second RGB pixel group includes a red pixel R7, a green pixel G7, and a blue pixel B7. The red pixel R6 and the green pixel G6 include a common, substantially continuous strip of orange emissive material **420** that spans respective driving terminals **402**, **404** for the red and green pixels R6, G6. A red filter **412** selectively transmits red light from the red pixel R6 while a green filter **414** selectively transmits green light from the green pixel G6. Similarly, the red pixel R7 and the green pixel G7 include a common, substantially continuous strip of orange emissive material **424** that spans respective driving terminals **432**, **434** for the red and green pixels R7, G7. A red filter **442** selectively transmits red light from the red pixel R7 while a green filter **444** selectively transmits green light from the green pixel G7. The blue pixels B6, B7 include a common, substantially continuous strip of blue emissive material **422** that spans respective driving terminals **406**, **436** for the blue pixels B6, B7. The blue pixels B6, B7 are situated between the adjacent red and green pixels R6, G6 in the first RGB pixel group and the adjacent red and green pixels R7, G7 in the second RGB pixel group.

[0071] The substantially continuous strips of orange emissive material **420** can be developed by placing a shadow mask with an elongated opening aligned over an area including the driving terminals **402**, **404** for the red and green pixels R6, G6 and depositing the orange emissive material **420** to form the substantially continuous strip with roughly uniform thickness while preventing the orange emissive material **420** from reaching the emissive regions for the blue pixels B6, B7. The elongated opening of the shadow mask (and thus the substantially continuous layer **420**) can optionally extend to span multiple alternating adjacent red and green pixels from additional RGB pixel groups (not shown). Further, the shadow mask can be arranged with an additional elongated opening aligned over an area including the driving terminals **432**, **434** for the red and green pixels R7, G7. Alternatively, the strip of orange emissive material **424** can be developed via a separate shadow mask.

[0072] Before and/or after the strips of orange emissive materials **420**, **424**, another shadow mask is placed over the display panel with an elongated opening in the shadow mask aligned over an area including the driving terminals **406**, **436** of the blue pixels B6, B7. The elongated opening in the shadow mask can extend to include emissive regions for additional blue pixels in the display panel such that the strip of blue emissive material **422** spans an area including multiple blue pixels and has a substantially constant thickness across the area. The shadow mask used to develop the strip of blue emissive material **422** can optionally be the same as the one used for the red and green pixels, but repositioned to align its elongated opening with the blue pixels B6, B7 while covering the red and green pixels R6, G6, R7, G7.

[0073] The red and green pixels R6, G6 of the first RGB pixel group can be adjacent pixels in a first row of a display panel. The blue pixels B6, B7 of the first and second RGB pixel groups can be adjacent pixels in a second row immediately above or below the red and green pixels R6, G6 of the first group. The red and green pixels R7, G7 of the second RGB pixel group can be adjacent pixels in a third row immediately adjacent the second row. Thus, the first and second pixel groups can span two columns and three rows of a display panel. Alternatively, the layout can be rotated by 90 degrees such that the two pixel groups include three columns and two rows.

[0074] In some examples of the layout **400**, each of the pixels R6-B6 and R7-B7 can have an approximately equal area and have approximately equally sized driving terminals. For example, the two pixel groups can be arranged as a rectangle divided into six approximately equally-sized squares arranged in a 2 by 3 array, with the upper two squares occupied by the red and green pixels R6, G6, the middle two squares occupied by the blue pixels B6, B7 and the lower two squares occupied by the red and green pixels R7, G7.

[0075] FIG. 4B is a top view of a layout **450** for an RGB multi-color pixel group similar to the layout of FIG. 4A, but where the blue pixels B6', B7' in each RGB multi-color pixel group have a larger area than either the red or green pixels R6, G6, R7, G7. As shown in the layout **450**, a blue emissive layer **452** is provided in a substantially continuous strip that includes the blue pixels B6', B7'. The blue pixels B6', B7' are driven via driving terminals **456**, **458** that are separately programmed and driven to cause the blue emissive layer to emit light according to independently determined luminance values. Thus, the driving terminals **456**, **458** define respective portions of the substantially continuous strip of blue emissive

material **452** included in the blue pixel **B6'** for the first RGB pixel group and the blue pixel **B7'** for the second RGB pixel group, respectively.

[0076] The red and green pixels **R6**, **G6**, **R7**, **G7** are each roughly as squares of dimension **d1**. The blue pixels **B6'**, **B7'** are each arranged as rectangles with a width approximately given by the widths of the red and green pixels **R6**, **G6**, **R7**, **G7** (e.g., **d1**) and a height given by **d2**, which is larger than **d1**. Thus, the areas of the two blue pixels **B6'**, **B7'** are each larger than the areas of the red and green pixels **R6**, **G6**, **R7**, **G7**. The width of the strip of blue emissive material **452** is larger than **d2** to allow for an alignment tolerance while still achieving nearly complete coverage of the driving terminals **456**, **458** of the blue pixels **B6'**, **B7'**. In an example, **d2** can be approximately twice **d1** such that the emissive region of each of the blue pixels **B6'**, **B7'** is roughly twice the area of the emissive regions of each of the red and green pixels **R6**, **G6**, **R7**, **G7**.

[0077] When patterning a display panel according to the layout **450**, the red and green pixels **R6**, **G6** can be immediately below another pair of red and green pixels for another RGB pixel group (not shown), and the orange emissive layer **420** can extend, along the width of the strip, to cover the other pair of red and green pixels. In some instances, the width dimensions of the alternating strips of orange and blue emissive material deposited on a display panel can be approximately equal, even where the blue pixels (e.g., **B6'**, **B7'**) are each roughly twice the area of each of the red and green pixels **R6**, **G6**, **R7**, **G7**, because the strips of orange emissive material (e.g., **420**, **424**) cover a region of red and green pixels that is two pixels wide (e.g., approximately twice the dimension **d1**, plus an alignment margin). The region of red and green pixels can be two rows of checkered red and green pixels, alternating adjacent pairs of red and green pixels, or some other regularly repeating pattern of red and green pixels.

[0078] Furthermore, while the blue pixels **B6'**, **B7'** are shown as extended along a vertical dimension **d2**, such that the blue pixels **B6'**, **B7'** are included in a single column, the present disclosure also applies to enlarged blue pixels that are rotated with an extended dimension roughly spanning a pair of red and green pixels. For example, the layout **450** can be modified with the blue pixels **B6'**, **B7'** pixels each rotated 90 degrees clockwise about an axis located centrally between the two. Thus, the first blue pixel **B6'** can be situated immediately below the red and green pixels **R6**, **G6** in the first RGB pixel group, and the blue pixel **B7'** can be situated immediately above the red and green pixels **R7**, **G7** in the second RGB pixel group.

[0079] FIG. 4C is a top view of a layout **460** for an RGB multi-color pixel group similar to the layout of FIG. 4B but where adjacent multi-color pixel groups share a common unitary blue pixel **B6/B7**. In the layout **460**, the common unitary blue pixel **B6/B7** can occupy roughly the same area as the combination of the blue pixels **B6'**, **B7'** in the layout **450** of FIG. 4B. The common unitary blue pixel **B6/B7** includes a single driving terminal **466** that is programmed according to a luminance value based on programming information for the first and second multi-color pixel groups. Thus, in the layout **460**, adjacent multi-color pixel groups share a single blue pixel (e.g., the blue pixel **B6/B7**), while still maintaining the distinct red and green pixels **R6**, **G6**, **R7**, **G7**. The common blue pixel **B6/B7** is driven to emit blue light with a luminance that is based on incoming blue content of a displayed image from the regions of the first and second pixel group. In some examples, the blue pixel **B6/B7** can be driven according to an

average blue luminance contribution from two adjacent RGB pixels corresponding to the first and second RGB pixel groups in the layout **460**.

[0080] FIG. 4D is a top view of a layout **470** for an RGB multi-color pixel group similar to the layout **450** of FIG. 4B with the red and green sub-pixels having elongated emissive regions. The alternating strips of orange emissive material **420**, **424** and blue emissive material **452** are situated as in the layout **450** shown in FIG. 4B. However, the strips of orange emissive material **420**, **424** are divided into red and green pixels (e.g., the pixels **R8**, **G8**, **R9**, **G9**) by rectangular driving terminals **482**, **484**, **493**, **495** elongated along the extended direction of the strip of orange emissive material **420**, **424**. The rectangular driving terminals **482**, **484**, **493**, **495** are situated to include two adjacent rows of the red and green pixels in the strip of orange emissive material **420**, **424**. Red color filters **472**, **474** and green color filters **492**, **494** are situated to selectively transmit the red content, and green content, respectively, emitted in the strips of orange emissive material **420**, **424**.

[0081] Thus, the rectangular driving terminals **482**, **484**, **493**, **495** are arranged in two adjacent rows of red and green pairs for each RGB pixel group. By contrast, the layout **450** includes alternating red and green square driving terminals in a single row. The red and green pixels **R8**, **G8**, **R9**, **G9** have a width spanning the two adjacent blue pixels **B8**, **B9** and a height dimension sufficiently small to allow the strip of orange emissive material **420** to overlap both red and green driving terminals **482**, **484**. In some examples, the red and green pixels **R8**, **G8**, **R9**, **G9** in the layout **470** have a height roughly half that of the red and green pixels **R6**, **G6**, **R7**, **G7** in the layout **450** of FIG. 4B, and have a width roughly twice that of the red and green pixels in the layout **450**.

[0082] FIG. 5 is a top view of a layout **500** for an RGB multi-color pixel group formed from parallel strips of red and green emissive materials **520**, **522** overlapped with perpendicularly aligned strips of blue emissive material **524**. The layout **500** includes a first RGB pixel group including a red pixel **R10**, a green pixel **G10**, and a blue pixel **B10**. The layout **500** also includes a second RGB pixel group including a red pixel **R11**, a green pixel **G11**, and a blue pixel **B11**. It is noted that the arrangement of the driving terminals in the layout **500** can be the same or similar as the arrangement of driving terminals in the layout **400** of FIG. 4A.

[0083] In reference to the layout **500** of FIG. 5, the red pixel **R10** is driven by a driving terminal **502** to convey current through the red emissive material **520**. The green pixel **G10** is driven by a driving terminal **504** to convey current through the green emissive material **522**. The blue pixel **B10** is driven by a driving terminal **506** to convey current through the red emissive material **520** and the blue emissive material **524**, which are arranged in a stacked configuration. The blue pixel **B11** is driven by a driving terminal **516** to convey current through the green emissive material **522** and the blue emissive material **524**, which are arranged in a stacked configuration.

[0084] Generally, the strip of blue emissive material **524** can be situated over or under the red and green emissive materials **520**, **522**. However, both strips of the red and green emissive material **520**, **522** are advantageously on the same side (e.g., over or under) of the blue emissive material **524** to provide efficiency in constructing a display panel including the pattern **500**. For example, a process can begin with depositing the strip of red emissive material **520** (or a pattern of such strips) on a display substrate via a shadow mask having

an elongated opening aligned to include the emissive region of the red pixels R10, R11 and the blue pixel B10. The shadow mask can then be translated by roughly the dimension of a single pixel such that the elongated opening is aligned to include the emissive region of the green pixels G10, G11 and the blue pixel B11, and the green emissive material 522 can be deposited. To develop the substantially continuous strip of blue emissive material 524 oriented perpendicularly to the two red and green strips 520, 522, the same shadow mask can be rotated about 90 degrees, or another shadow mask can be positioned over the display substrate with an elongated opening aligned to include the emissive regions of the blue pixels B10, B11, and the blue emissive material 524 can be deposited. Because the translation of the shadow mask while maintaining a parallel orientation of the shadow mask's elongated opening is generally a faster process than either rotating a shadow mask or positioning a different shadow mask, the substantially continuous strips of red and green emissive material 520, 522 are desirably deposited consecutively.

[0085] A blue color filter 508 is situated to selectively transmit the blue content from the light emitted in the blue pixels B10, B11. In some examples, the blue color filter 508 can be applied to continuously span a row of adjacent blue pixels including the blue pixels B10, B11. In reference to the layout 500 of FIG. 5, it is noted that the only pixels in the RGB pixel groups that are filtered are the blue pixels B10, B11, while the red and green pixels emit unfiltered light. The net luminance of a typical display is dominantly provided by red and green color contributions, with blue light contributions providing much less light overall (perhaps as little as 3% in total luminance contributions in a typical display). Furthermore, the human retina is generally more sensitive ("responsive") to red and green light than blue light and so bright images can be perceived while relying primarily on red and green color contributions to a given image. Thus, by filtering the blue pixels, rather than the red or green pixels, there is relatively little light that is wastefully generated only to be blocked by a color filter. Accordingly, the layout 500 provides for a relatively high degree of energy efficiency by filtering only the blue light contributions to the total luminance and emitting the red and green contributions to the total luminance without significant color filters to partially block the light generated in those regions.

[0086] FIG. 6A is a top view of a layout 600 for RGB multi-color pixel groups formed from parallel strips of red and green emissive materials 620, 622 overlapped with perpendicularly aligned strips of blue emissive material 625, 626 and with blue pixels B12, B13 enlarged relative to red and green sub-pixels R12, G12, R13, G13. FIG. 6B is an aspect view of the RGB multi-color pixel groups of FIG. 6A showing alignment of the layers of emissive material 620, 622, 624, 626 and color filters 608, 618 with respect to a TFT backplane 630.

[0087] In the layout 600, a first RGB pixel group includes a red pixel R12, a green pixel G12, and a blue pixel B12, and a second RGB pixel group includes a red pixel R13, a green pixel G13, and a blue pixel B13. Substantially continuous parallel strips of red emissive material 620 and green emissive material 622 are arranged over the red pixels R12, R13 and green pixels G12, G13, respectively. The strips of red and green emissive material 620, 622 also extend over a portion of the blue pixels B12, B13. A substantially continuous strip of blue emissive material 625 is oriented perpendicularly to the red and green strips 620, 622 and covers the blue pixel B12.

Another substantially continuous strip of blue emissive material 626 is also oriented perpendicularly to the red and green strips 620, 622 and covers the blue pixel B13.

[0088] In the first RGB pixel group, the red pixel R12 includes a driving terminal 602 for conveying current through the red emissive material 620; the green pixel G12 includes a driving terminal 604 for conveying current through the green emissive material 622; and the blue pixel B12 includes a driving terminal 606 for conveying current through the blue emissive material 625, the red emissive material 620, and the green emissive material 622. A blue color filter 608 is situated to selectively transmit the blue light from the blue pixel B12 (e.g., by blocking the red and green light from the portions of the red and green emissive materials overlapping the driving terminal 606). In the second RGB pixel group, the red pixel R13 includes a driving terminal 612 for conveying current through the red emissive material 620; the green pixel G13 includes a driving terminal 614 for conveying current through the green emissive material 622; and the blue pixel B13 includes a driving terminal 616 for conveying current through the blue emissive material 625, the red emissive material 620, and the green emissive material 622. A blue color filter 608 is situated to selectively transmit the blue light from the blue pixel B12 (e.g., by blocking the red and green light from the portions of the red and green emissive materials overlapping the driving terminal 606). As shown in FIGS. 6A-6B, the first RGB pixel group is roughly arranged as a square with the red and green pixels R12, G12 each occupying roughly one quadrant of the square and the blue pixel B12 approximately occupying the remaining half of the square. Similarly, the second RGB pixel group is roughly arranged as a square with the red and green pixels R13, G13 each occupying roughly one quadrant of the square and the blue pixel B13 approximately occupying the remaining half of the square.

[0089] While the arrangement of the overlapping emissive regions in the layout 600 is distinct from other layouts disclosed herein, it is noted that the arrangement of the driving terminals in the layout 600 of FIGS. 6A-6B can be the same or similar to the arrangement of the driving terminals in the layout 300 of FIG. 3A. Thus, the ratio of areas of the display panel occupied by red, green, and blue pixels in a display panel patterned according to the layout 600 can be the same or similar to a display panel patterned according to either the layout 300. Furthermore, the discussions above regarding the relative size ("area") of the blue emissive region with respect to the red and green emissive regions in the layout 300 for the RGB pixel group so as to mitigate the aging degradation of the display also applies to the layout 600 of FIGS. 6A-6B.

[0090] High resolution display panels and/or display systems can be constructed according to any of the layouts disclosed herein by patterning the layouts across a display panel to create a regularly repeating pattern of evenly distributed red, green, blue, and/or white emitting pixels that are separately programmed.

[0091] Generally, the physical dimensions of the multi-color pixel groups described herein can be selected for a particular implementation once constraints for total display size, and display resolution are known. By way of example, a display size 3 inches wide by 1.69 inches high with a resolution of 1920 by 1080 pixels, each multi-color pixel group is roughly situated in an area given by a square with sides roughly 0.0016 inches (or roughly 40 μm). For the same display size with a resolution of 1280 by 720 pixels, each multi-color pixel group is roughly situated in an area given by

a square with sides roughly 0.0023 inches (or roughly 60 μm). Thus, achieving such displays generally require pixel pitch of approximately 40-80 μm , which corresponds to pixel densities approaching, or even exceeding, 300 pixels per inch.

[0092] The exemplary layouts disclosed herein are described as oriented along rows and/or columns for purposes of clarity in referring to arranging the layouts on a display panel. However, it is specifically understood that any of the layouts described herein can be rotated by 90 degrees and references to rows/columns described herein therefore apply equally to similar descriptions referring to columns/rows of a display panel.

[0093] Circuits disclosed herein generally refer to circuit components being connected or coupled to one another. In many instances, the connections referred to are made via direct connections, i.e., with no circuit elements between the connection points other than conductive lines. Although not always explicitly mentioned, such connections can be made by conductive channels defined on substrates of a display panel such as by conductive transparent oxides deposited between the various connection points. Indium tin oxide is one such conductive transparent oxide. In some instances, the components that are coupled and/or connected may be coupled via capacitive coupling between the points of connection, such that the points of connection are connected in series through a capacitive element. While not directly connected, such capacitively coupled connections still allow the points of connection to influence one another via changes in voltage which are reflected at the other point of connection via the capacitive coupling effects and without a DC bias.

[0094] Furthermore, in some instances, the various connections and couplings described herein can be achieved through non-direct connections, with another circuit element between the two points of connection. Generally, the one or more circuit element disposed between the points of connection can be a diode, a resistor, a transistor, a switch, etc. Where connections are non-direct, the voltage and/or current between the two points of connection are sufficiently related, via the connecting circuit elements, to be related such that the two points of connection can influence each other (via voltage changes, current changes, etc.) while still achieving substantially the same functions as described herein. In some examples, voltages and/or current levels may be adjusted to account for additional circuit elements providing non-direct connections, as can be appreciated by individuals skilled in the art of circuit design.

[0095] Any of the circuits disclosed herein can be fabricated according to many different fabrication technologies, including for example, poly-silicon, amorphous silicon, organic semiconductor, metal oxide, and conventional CMOS. Any of the circuits disclosed herein can be modified by their complementary circuit architecture counterpart (e.g., n-type transistors can be converted to p-type transistors and vice versa).

[0096] While particular embodiments and applications of the present invention have been illustrated and described, it is to be understood that the invention is not limited to the precise construction and compositions disclosed herein and that various modifications, changes, and variations can be apparent from the foregoing descriptions without departing from the spirit and scope of the invention as defined in the appended claims.

1. A high resolution display panel comprising:

a display substrate including a plurality of driving circuits each including a drive transistor coupled to an electrode

such that the substrate includes a plurality of electrodes each coupled to a respective drive transistor;

a first substantially continuous emissive organic layer deposited in a first area of the display panel including at least two of the plurality of electrodes, the first emissive organic layer configured to emit light according to a first color spectrum responsive to current being conveyed through the first emissive organic layer;

a second substantially continuous emissive organic layer deposited in a second area of the display panel including at least two of the plurality of electrodes, the second emissive organic layer configured to emit light according to a second color spectrum responsive to current being conveyed through the second emissive organic layer; and

one or more first color filters situated to partially block light emitted from at least one of the first or the second emissive organic layers such that light transmitted through the one or more first color filters is characterized by a color spectrum for a first fundamental color.

2. The high resolution display panel according to claim 1, wherein the first area and the second area overlap in an overlapped region including at least one electrode of the plurality of electrodes such that the first emissive organic layer and the second emissive organic layer are stacked in the overlapped region and configured to both emit light responsive to current being conveyed via the at least one electrode.

3. The high resolution display panel according to claim 1, wherein the first area includes a plurality of adjacent electrodes in a first row or column without including electrodes not in the first row or column, and wherein the second area includes a plurality of adjacent electrodes in a second row or column without including electrodes not in the second row or column.

4. The high resolution display panel according to claim 1, wherein the first area and the second area each have an extended dimension greater than a width dimension, and wherein the extended dimensions of the first and second areas are oriented in parallel.

5. The high resolution display panel according to claim 1, wherein the first area and the second area each have an extended dimension greater than a width dimension, and wherein the extended dimensions of the first and second areas are oriented perpendicularly.

6. The high resolution display panel according to claim 1, further comprising a third substantially continuous emissive organic layer deposited in a third area of the display panel including at least two of the plurality of electrodes, the second emissive organic layer configured to emit light according to a third color spectrum responsive to current being conveyed through the third emissive organic layer.

7. The high resolution display according to claim 6, wherein the first, second, and third emissive layers, and the one or more first color filters, are arranged such that the first fundamental color, a second fundamental color, and a third fundamental color are emitted from the display panel via three respective subsets of pixels arranged in a regularly repeating pattern across the display panel, each subset of pixels corresponding to a first, second, and third distinct subset of the plurality of electrodes, respectively.

8. The high resolution display according to claim 7, wherein the first fundamental color is blue and a plurality of

pixels in a blue subset of pixels are configured to emit blue light, the second fundamental color is green and a plurality of pixels in a green subset of pixels are configured to emit green light, and the third fundamental color is red and a plurality of pixels in a red subset of pixels are configured to emit red light,

wherein the first emission layer is configured to emit blue light and the first area includes pixels in the blue subset, wherein the second emission layer is configured to emit red light and the second area includes pixels in the red subset and the blue subset such that one or more pixels in the blue subset include a stack of blue and red emission layers,

wherein the third emission layer is configured to emit green light and the third area includes pixels in the green subset and the blue subset such that one or more pixels in the blue subset include a stack of blue and green emission layers, and

wherein the one or more first color filters are situated to filter light from the pixels in the blue subset and are configured to selectively transmit blue content from the blue, red, and green light emitted from the emission layers of the pixels in the blue subset.

9. The high resolution display panel according to claim 8, wherein the regularly repeating patterns of the pixels in the red, green, and blue subsets are arranged such that the pixels in the blue subset occupy a larger surface area of the display panel than the pixels in either the red subset or the green subset.

10. The high resolution display panel according to claim 8, wherein the first subset of electrodes corresponding to the pixels in the blue subset each occupy a larger region of the display substrate than each of the electrodes in the second or third subsets.

11. The high resolution display panel according to claim 1, further comprising:

one or more second color filters situated to partially block light emitted from at least one of the first or the second emissive organic layers such that light transmitted through the one or more color filters is characterized by a color spectrum for a second fundamental color.

12. The high resolution display panel according to claim 11, wherein the first and the second emissive layers, the one or more first color filters, and the one or more second color filters are arranged such that the first fundamental color, the second fundamental color, and a third fundamental color are emitted from the display panel via three respective subsets of pixels arranged in a regularly repeating pattern across the display panel, each subset of pixels corresponding to a first, second, and third distinct subset of the plurality of electrodes, respectively.

13. The high resolution display panel according to claim 12, wherein the first fundamental color is red and a plurality of pixels in a red subset of pixels are configured to emit red light, the second fundamental color is green and a plurality of pixels in a green subset of pixels are configured to emit green light, and the third fundamental color is blue and a plurality of pixels in a blue subset of pixels are configured to emit blue light,

wherein the first emission layer is configured to emit orange light, the first area including pixels in the red and green subsets, the one or more first color filters configured to selectively transmit red contributions to the emitted orange light and situated to filter light from the pixels in the red subset, the one or more second color filters

configured to selectively transmit green contributions to the emitted orange light and situated to filter light from the pixels in the green subset, and

the second emission layer being configured to emit blue light, the second area including pixels in the blue subset.

14. The high resolution display panel according to claim 13, wherein the pixels in the red and green subsets that share a common orange emission layer correspond to a row or column of electrodes in the display substrate alternating between electrodes for red pixels and electrodes for green pixels such that a width of the first area spans the row or column of electrodes.

15. The high resolution display panel according to claim 13, wherein the pixels in the red and green subsets that share a common orange emission layer correspond to first and second adjacent lines of elongated electrodes in the back-plane, the first line including electrodes for red pixels, the second line including electrodes for green pixels such that a width of the first area spans the adjacent lines of elongated electrodes.

16. The high resolution display panel according to claim 12, wherein the first and the second emissive layers, the one or more first color filters, the one or more second color filters, and one or more third color filters are further arranged such that a fourth fundamental color is transmitted from the display panel via a fourth subset of pixels corresponding to a fourth distinct subset of the plurality of electrodes.

17. The high resolution display panel according to claim 16, wherein the first fundamental color is red and a plurality of pixels in a red subset are configured to emit red light, the second fundamental color is green and a plurality of pixels in a green subset are configured to emit green light, the third fundamental color is blue and a plurality of pixels in a blue subset are configured to emit blue light, and the fourth fundamental color is white and a plurality of pixels in a white subset are configured to emit white light,

wherein the first emission layer is configured to emit orange light, the first area including pixels in the red, green, blue, and white subsets, the one or more first color filters configured to selectively transmit red contributions to the emitted orange light and situated to filter light from the pixels in the red subset, the one or more second color filters configured to selectively transmit green contributions to the emitted orange light and situated to filter light from the pixels in the green subset,

the second emission layer being configured to emit blue light, the second area including pixels in the blue and white subsets such that the pixels in the blue and white subsets include a stack of orange and blue emission layers, the one or more third color filters configured to selectively transmit blue contributions to the emitted blue and orange light and situated to filter light from the pixels in the blue subset, the pixels in the white subset configured to emit combined blue and orange light to form white light.

18. The high resolution display panel according to claim 17, wherein the regularly repeating patterns of the pixels in the red, green, and blue subsets are arranged such that the pixels in the blue subset occupy a larger surface area of the display panel than the pixels in either the red subset or the green subset.

19. The high resolution display panel according to claim 17, wherein the first subset of electrodes corresponding to the

pixels in the blue subset each occupy a larger region of the backplane than each electrode in the second or third subsets.

20. The high resolution display panel according to claim 12, wherein the regularly repeating pattern of each of the subsets of pixels is arranged at a density exceeding 300 pixels per inch.

21. The high resolution display panel according to claim 12, wherein the regularly repeating pattern of each of the subsets of pixels is arranged at a density of approximately 300 pixels per inch.

22. The high resolution display panel according to claim 1, wherein the display substrate is a backplane of the display panel and the first and the second emissive organic layers are deposited over the backplane, the one or more color filters applied over the at least one of the first or the second emissive organic layers, and wherein the high resolution display panel further includes an encapsulation substrate enclosing the first and the second emissive organic layers.

23. The high resolution display panel according to claim 1, further comprising a controller for operating the backplane to program each driving circuit according to programming information such that storage capacitors in each driving circuit are charged according to programming voltages conveyed via data lines during programming cycles and the drive transistors convey currents through the plurality of electrodes and the corresponding emission layers during emission cycles to emit light from the display panel according to the programming information.

24. A method of fabricating a high resolution display panel including a display substrate with a plurality of driving circuits conveying currents to a plurality of electrodes via drive transistors and an emission region receiving the currents from the plurality of electrodes, the method comprising:

depositing a first substantially continuous emissive organic layer with a substantially constant thickness in a first area of the display panel including at least two of the plurality of electrodes, the first emissive organic layer configured to emit light according to a first color spectrum responsive to current being conveyed through the first emissive organic layer;

depositing a second substantially continuous emissive organic layer with a substantially constant thickness in a second area of the display panel including at least two of the plurality of electrodes, the second emissive organic layer configured to emit light according to a second color spectrum responsive to current being conveyed through the second emissive organic layer; and

situating one or more first color filters situated to partially block light emitted from at least one of the first or the second emissive organic layers such that light transmitted through the one or more first color filters is characterized by a color spectrum for a first fundamental color.

25. The method of fabricating a high resolution display panel according to claim 24, further comprising:

prior to the depositing the first emissive organic layer, positioning a shadow mask over the display panel such that an elongated opening in the shadow mask corresponding to the first area is aligned over a plurality of the electrodes in a first row or column of the plurality of electrodes, such that the first emissive organic layer is developed with a substantially constant thickness throughout the first area over the plurality of the electrodes in the first row or column.

26. The method of fabricating a high resolution display panel according to claim 25, further comprising:

prior to the depositing the second emissive organic layer, positioning the shadow mask or another shadow mask over the display panel such that the elongated opening in the shadow mask corresponds to the second area, or another elongated opening in the shadow mask or the other shadow mask corresponding to the second area, is aligned over a plurality of the electrodes in a second row or column of the plurality of electrodes, such that the second emissive organic layer is developed with a substantially constant thickness throughout the second area over the plurality of the electrodes in the second row or column.

27. The method of fabricating the high resolution display panel according to claim 26, wherein the first area and the second area each have an extended dimension greater than a width dimension, and wherein the positioning of the shadow mask prior to the depositing the first and second emissive organic layers is carried out such that the extended dimensions of the first and second areas are oriented in parallel.

28. The method of fabricating the high resolution display panel according to claim 26, wherein the first area and the second area each have an extended dimension greater than a width dimension, and wherein the positioning of the shadow mask prior to the depositing the first and second emissive organic layers is carried out such that the extended dimensions of the first and second areas are oriented perpendicularly.

29. The method of fabricating the high resolution display panel according to claim 23, further comprising:

depositing a third substantially continuous emissive organic layer with a substantially constant thickness in a third area of the display panel including at least two of the plurality of electrodes, the third emissive organic layer configured to emit light according to a third color spectrum responsive to current being conveyed through the third emissive organic layer, and

wherein the first area is overlapped by at least one of the second area or the third area in an overlapped region including at least one electrode of the plurality of electrodes and at least one of the one or more color filters is situated to partially block light emitted from the overlapped region.

30. A high resolution display system comprising:

a display substrate;

a first multi-color pixel group situated on the display substrate and including:

a first pixel circuit including a first emission region and a driving circuit having a drive transistor and a storage capacitor configured to convey current through the emission region via the drive transistor according to a charge on the storage capacitor;

a second pixel circuit including a second emission region and a driving circuit having a drive transistor and a storage capacitor configured to convey current through the emission region via the drive transistor according to a charge on the storage capacitor;

a first substantially continuous emissive layer deposited with a substantially constant thickness in a first area including the first emission region and the second emission region, the first emissive layer configured to emit

light according to a first color spectrum responsive to current being conveyed through the first emissive layer; and

a first color filter situated to partially block light emitted from the first emission region such that light of a first fundamental color is transmitted through the first color filter; and

a controller configured to program the driving circuits of the first and second pixel circuits according to programming information during a programming cycle such that the pixel circuits emit light according to the programming information during a driving cycle following the programming cycle.

31. The high resolution display system according to claim **30**, wherein the first multi-color pixel group further comprises a second substantially continuous emissive layer deposited with a substantially constant thickness in a second area including the first emission region such that the first and second emissive layers are stacked in the first emission region and configured to both emit light responsive to current being conveyed via the driving circuit of the first pixel circuit,

wherein the second emissive layer is configured to emit light according to a second color spectrum, and

wherein the first color filter is configured to block at least a portion of the light emitted from the first and second emissive layers.

32. The high resolution display system according to claim **30**, wherein the first multi-color pixel group further comprises:

a third pixel circuit including a third emission region and a driving circuit having a drive transistor and a storage capacitor configured to convey current through the emission region via the drive transistor according to a charge on the storage capacitor; and

a second substantially continuous emissive layer deposited with a substantially constant thickness in a second area including the third emission region, the second emissive layer configured to emit light according to a second color spectrum responsive to current being conveyed through the second emissive layer.

33. The high resolution display system according to claim **32**, further comprising a second color filter situated to partially block light emitted from the second emission region such that light of a second fundamental color is transmitted through the second color filter.

34. The high resolution display system according to claim **33**, wherein the first color spectrum includes orange light, and the first and second color filters selectively transmit red and green contributions to the orange light, respectively, and

wherein the second color spectrum includes blue light and the third pixel circuit emits unfiltered blue light.

35. The high resolution display system according to claim **32**, wherein the first pixel group is arranged with the third emission region occupying more of the area of the first pixel group than either of the first or second emission regions.

36. The high resolution display system according to claim **32**, wherein the first and second emission region occupy distinct areas of the first pixel group on the display substrate, the distinct areas being defined by respective driving terminals of the first and second pixel circuit.

37. The high resolution display system according to claim **32**, wherein the first pixel group is arranged approximately in a square on the display substrate with the first and second emission regions each occupying approximately one quadrant of the square and the third emission region occupying the remaining half of the square.

38. The high resolution display system according to claim **32**, wherein the first pixel group is arranged approximately in a square on the display substrate with the third emission region occupying approximately one half of the square and the first and second emission regions jointly occupying the remaining half of the square with each of the first and second emission regions having an elongated dimension roughly the size of a side of the square, and a width dimension roughly the size one one-quarter the side of the square.

39. The high resolution display system according to claim **32**, wherein the first color spectrum includes orange light, the first color filter selectively transmits red light, and the second color filter selectively transmits green light.

40. The high resolution display system according to claim **30**, further comprising a second multi-color pixel group arranged similarly to the first pixel group and located adjacent the first pixel group on the display substrate such that the first and second emissive layers are shared by the first and second pixel groups.

41. The high resolution display system according to claim **40**, wherein the first and second emissive layers are substantially continuous layers that are situated in both the first and second pixel groups.

42. The high resolution display system according to claim **30**, further comprising a plurality of pixel groups similar to the first pixel group patterned across the display substrate so as to provide a regularly repeating pattern of multi-color pixel groups.

43. The high resolution display system according to claim **42**, wherein the regularly repeating pattern of multi-color pixel groups is arranged on the display substrate with a density of approximately 300 pixels per inch.

44. The high resolution display system according to claim **32**, further comprising a plurality of pixel groups similar to the first pixel group patterned across the display substrate so as to provide a regularly repeating pattern of multi-color pixel groups.

45. The high resolution display system according to claim **42**, wherein the regularly repeating pattern of multi-color pixel groups is arranged on the display substrate with a density of approximately 300 pixels per inch.

46. The high resolution display system according to claim **30**, wherein the first emissive layer includes an organic emissive material.

摘要(译)

用于高分辨率有源矩阵显示器的装置包括不同颜色的有机发光层，每个有机发光层沉积在连续区域上，以便包括多于一个像素发光区域。设置滤色器以部分地阻挡来自至少一些发光区域的光，使得主要的附加颜色从不同的像素子集发射。发光层可以沿着显示器的行或列以交替的平行条纹沉积，或者可以相对于彼此垂直取向，使得发光层在至少一些像素的发光区域中重叠。在一些示例中，像素的红色，绿色和蓝色以规则图案布置在显示器上，并且蓝色像素的发光区域形成比红色或绿色像素更大的显示区域。
