Description

Related Application

[0001] This application is based on and claims the benefit of the filing date of US application no. 60/825,597 filed 14 September 2006.

Field of the Invention

[0002] The present invention relates to a method and apparatus for providing scanning with a light transmitter (such as an optical fibre), of particular but by no means exclusive application in microscopy, endoscopy (including endomicroscopy), and confocal microscopy and endoscopy.

Background of the Invention

[0003] Some existing microscopes and endoscopes employ one or more optical fibre for light delivery to a sample and light collection from the sample. To image the sample, the delivered light is scanned across the sample; by scanning the exit tip of the fibre, this can be done by scanning the light after its emission by the fibre, or by providing multiple return fibres and collecting light sequentially from each.

[0004] The scanning of the fibre can be effected by attaching the exit tip of the fibre to a mechanical actuator, such as a vibrating tine of a tuning fork. Alternatively, one existing approach employs an actuator located at the base of a fibre, to impart a scanning motion to the fibre and hence its tip.

[0005] For example, four background art scanning mechanisms 10, 12, 14, 16 for use in small diameter endoscopes are shown in figures 1A to 1D respectively. Scanning mechanisms 10 and 12 of figures 1A and 1B each include an asymmetric fork 18 of ferromagnetic material to carry an optical fibre (not shown). A first (scanning) tine of fork 18 is axially located and a fixed X drive coil 20 surrounds both scanning tine and the second (balancing) tine. A Y scan is obtained by a see-saw action whereby the fork 18 rocks inside the X coil 20. The driving force for the Y scan is obtained with a permanent magnet 22 and an electromagnet 24 that carries a Y drive current. In scanning mechanism 12 of figure 1B, the magnetic circuit is folded to reduce overall length, and the Y coil 24 is hollow.

[0006] Synchronisation in both scanning mechanisms 10 and 12 is obtained with a piezo sensor mounted at the base of fork 18, which is used to drive the fork at resonance through an amplifier. The X scan in both mechanisms is sinusoidal, and usually the central half of the mechanical scan is used for imaging. The outer scan region, where the fibre tip slows down and reverses, is discarded.

[0007] Scanning mechanism 14 of figure 1C is the base excited cantilever using a tube piezo driver. This layout

is seen in scanning microscopes, bar-code scanners, and a spiral scanning endoscope developed at the University of Washington. Such systems appear, however, to suffer from problems in the control of scan distortion.

[0008] Referring to figure 1D, scanning mechanism 16 - disclosed in WO 04/40267 - includes a slotted magnet 26 attached to a fibre 28 near the base 30 of the fibre, such that the fibre acts as a vibrating cantilever. The magnet 26 is activated and controlled by four electromagnets or coils 32 that surround the magnet.

[0009] Examples of some of these scanning systems are disclosed in US Patent No. 6,294,775, US Patent No. 6,975,898 and US Patent No. 6,845,190.

[0010] A method according to the preamble of claim 1 is disclosed in WO 2004/040267 A.

Summary of the Invention

[0011] According to a first broad aspect, therefore, the invention provides a method of scanning a light transmitter having an exit tip according to claim 1.

[0012] In one particular embodiment, the method includes vibrating the light transmitter in the first direction at the first overtone (also referred to as the second order of vibration) of mechanical resonance.

[0013] The method may include:

driving the light transmitter with an axially polarised magnet mounted on the light transmitter (such as near the mount), a first pair of axially oriented electromagnetic coils located on either side of the magnet in the first direction comprising a drive coil for driving the magnet in the first direction and a sensor coil for providing a signal for use in generating a position signal indicative of the position of the magnet in the first direction, and a second pair of axially oriented electromagnetic coils located on either side of the magnet in the second direction for driving the magnet in the second direction; and using the position signal to provide positive feedback to maintain light transmitter vibration in the first direction (and optionally for synchronising an image display).

[0014] In one embodiment, the method includes deriving the position signal by integrating the output signal of the sensor coil.

[0015] In a particular embodiment, the method may include subtracting a signal proportional to the drive current from the position signal to compensate for contamination of the position signal by a current induced in the sensor coil by the magnetic field of the drive coil.

[0016] In these embodiments, the magnet may be tapered in the second direction to maximize the volume of the magnet that can be accommodated between the second first pair of electromagnetic coils (owing to the rotation of the magnet as it is scanned in that direction). However, the magnet may be less tapered or untapered in

the first direction (owing to the almost parallel motion of the magnet in the first direction when position at or near the antinode).

[0017] In other embodiments, additional coils may be employed for driving the light transmitter in the first direction, the second direction, or in both the first direction and second directions.

[0018] In one embodiment, the method includes locating the magnet substantially at a vibration antinode so that the magnet moves laterally without significant rotation, or substantially at a minimum in the overtone frequency versus magnet position curve to minimize required light transmitter length. In another embodiment, the method includes locating the magnet substantially at both a vibration antinode and a minimum in the overtone frequency versus magnet position curve.

[0019] For such magnet locations the resultant fundamental resonant frequency may be too low for the desired frequencies (such as require in some scanners), so it becomes desirable to employ an overtone resonance (e.g. the first overtone), such as at around four times the frequency.

[0020] The method may include vibrating the light transmitter in the second direction non-resonantly with low frequency alternating current excitation of the second pair of coils.

[0021] That is, the magnetic force available in some compact scanners may be limited, so the magnet may in some embodiments be removed from the mounting point of the light transmitter (or base) to obtain sufficient bending moment for tip desired deflection (particularly if driven in that direction with low frequency alternating current excitation and non-resonant operation).

[0022] In an alternative embodiment, the method includes vibrating the light transmitter in the second direction non-resonantly with varying direct current excitation of the second pair of coils. In such an embodiment, the method may include providing a restorative force (for restoring the light transmitter) with a spring or with the resilience of the light transmitter.

[0023] The light transmitter typically comprises an optical fibre, which may be single moded but need not be, according to application. Alternatively it may comprise a plurality of fibres or a fibre bundle, where each fibre may be single moded or otherwise.

[0024] The method may include providing negative feedback at the fundamental frequency in both first and second directions.

[0025] This would be done because a low fundamental resonance frequency creates a susceptibility to external vibrations, and any signals around this frequency in a linear drive.

[0026] The method may include mounting the light transmitter on a thin transverse beam. The predominantly torsional strain of this beam provides the additional compliance to lower the resonant frequency in one direction.

[0027] In another embodiment, the method includes mounting the light transmitter on a cantilever with a lower

resonant frequency in one (e.g. y) direction than in the other (e.g. x) directions.

[0028] According to a second broad aspect, the invention provides a scanning apparatus according to claim 17.

[0029] The apparatus may include a drive comprising:

an axially polarised magnet mounted on the light transmitter (such as near the mount);

a first pair of axially oriented electromagnetic coils located on either side of the magnet in the first direction comprising a drive coil for driving the magnet in the first direction and a sensor coil for providing a signal for use in generating a position signal indicative of the position of the magnet in the first direction; and

a second pair of axially oriented electromagnetic coils located on either side of the magnet in the second direction for driving the magnet in the second wherein the position signal is suitable for providing feedback to maintain light transmitter vibration in the first direction (and optionally for synchronising an image display).

[0030] In one embodiment, the apparatus includes an integrator for integrating the output signal of the sensor coil to generate the position signal.

[0031] In a particular embodiment, the apparatus is configured to subtract a signal proportional to the drive current from the position signal to compensate for contamination of the position signal by a current induced in the sensor coil by the magnetic field of the drive coil.

[0032] In these embodiments, the magnet may be tapered in the second direction to maximize the volume of the magnet that can be accommodated between the second first pair of electromagnetic coils. However, the magnet may be less tapered or untapered in the first direction.

[0033] In one embodiment, the magnet is located substantially at a vibration antinode so that the magnet moves laterally without significant rotation, or substantially at a minimum in the overtone frequency versus magnet position curve, or substantially at both a vibration antinode and a minimum in the overtone frequency versus magnet position curve.

[0034] The apparatus may be configured to vibrate the light transmitter in the second direction non-resonantly with low frequency alternating current excitation of the second pair of coils.

[0035] In other embodiments, the apparatus includes a source of varying direct current for exciting the second pair of coils and thereby vibrate the light transmitter in the second direction non-resonantly. In such embodiments, a restorative force may be provided by the resilience of the light transmitter, or the apparatus may include a spring or other resilient mechanism for providing a restorative force.

[0036] The light transmitter typically comprises an optical fibre. Alternatively it may comprise a plurality of fibres or a fibre bundle.

[0037] The mount for the light transmitter may comprise a thin transverse beam or a cantilever.

[0038] The apparatus may include an imaging system for processing return light from the light transmitter and displaying an image generated therefrom.

[0039] The invention also provides an imaging apparatus comprising a scanning apparatus as described above, such as a microscope, an endoscope, an endomicroscope or an optical coherence tomograph.

[0040] In some embodiments the imaging apparatus is a confocal imaging apparatus, such as a confocal microscope or a confocal endoscope or a multiphoton endoscope.

Brief Description of the Drawing

[0041] In order that the invention may be more clearly ascertained, embodiments will now be described, by way of example, with reference to the accompanying drawing, in which:

Detailed Description

[0042] A scanner according to a first embodiment of the present invention is shown schematically at 40 in figure 2A, which is a cross sectional side view of the scanner. Scanner 40 is adapted for use as the scanning mechanism of an endoscope, and includes a flexible optical transmitter in the form of a standard optical fibre 42 mounted in a mount 44 and surrounded by a generally cylindrical housing 46.

[0043] It should be noted that the flexible optical transmitter may alternatively be in the form of a fibre bundle, but in the following description, for simplicity, it will be referred to as "fibre 42" rather than as "fibre or fibres 42", though it should be understood that the latter may be appropriate in some embodiments.

[0044] The scanner 40 also includes a permanent magnet 48 mounted on fibre 42, at approximately a quarter of the length of the fibre from mount 44. The precise location of magnet 48 is discussed in detail below. The magnet can be mounted in any suitable way, including by locating the fibre in an aperture through the magnet or in a slot in one lateral face of the magnet; the magnet will typically be held in place with glue. In this embodiment magnet 48 has a slot (not shown) in its upper face, in which the fibre is located and held by glue.

[0045] The length of fibre 42 from mount 44 to magnet 48 is about 4 mm, and from mount to fibre tip 18 mm; the fibre 42 has a diameter of approximately 125 micron. The length of magnet 48 is about 2 mm. This geometry is suitable in view of the stiffness of a standard fibre of these dimensions. The distance of magnet 48 from mount 44 is greater than might be expected, but is employed to obtain the desired Y deflection without the benefit of mechanical Q. As a result the fundamental resonance frequency (of about 200 Hz) is relatively low and may not be suitable for imaging in some applications. This frequency also leads to sensitivity to unwelcome interference due to ringing in response to external vibrations. In

addition, a fast Y retrace can induce long term ringing which carries over into a displayed image. The direct relationship between gravitational deflection and resonance frequency is discussed in more detail below.

[0046] The scanner 40 includes a drive in the form of four electromagnetic coils 50 located around magnet 48 spaced equally from each other, inside interior wall 52 of housing 46. The four coils comprise two Y coils 54a, 54b (shown in this figure) and two X coils (not shown) aligned in a plane perpendicular to the plane of the Y coils.

Each coil has an elliptical cross section and is wound about a silicon steel or permalloy core (e.g. core 55a of coil 54a); each core has an elliptical cross section of ~0.8 mm major axis and ~0.4 mm minor axis, and in one particular embodiment a 0.7 mm major axis and a 0.3 mm minor axis. The coils abut the interior wall of cylindrical housing 46, and are supported by their cores; the cores are in turn attached to and supported by a frame (not shown) - to which the fibre mount 44 is also attached - around which the housing 46 is fitted.

[0047] As is explained in greater detail below, the fibre 42 is driven resonantly in the x direction (the 'fast scan') with an operating frequency of about 850 Hz, using the first overtone (automatically selected by the electronics). The orthogonal (i.e. y) direction is scanned in a non-resonant manner using a low frequency alternating current drive.

[0048] Though discussed in greater detail below, briefly, overtone operation in the x direction is obtained by using one X coil (referred to as the X drive coil) to produce the driving force, and the other X coil as a sensor (the X sensor coil). The emf induced in the X sensor coil is approximately proportional to the magnet velocity, and this induced voltage is electronically integrated to provide feedback information. There is also a directly induced voltage from the X drive coil. This is cancelled by sampling the drive current and subtracting a balancing proportion from the integrated waveform.

[0049] The signal proportional to the movement of the magnet 48 is used both for positive feedback after phase shifting to keep the fibre 42 vibrating, and also for synchronising an image display if - as would be usual - the output of scanner 40 is ultimately coupled to such a display. A frequency selective filter is included in the feedback path to prevent oscillation at the fundamental frequency of the cantilever. This arrangement is self-starting at the required overtone.

[0050] Y coils 54a, 54b provide vibration in the y direction; they provide balance and the required greater force needed for non-resonant scanning. The symmetry also reduces any direct induction into the X sensor coil, and the resonant drive signal into Y coils 54a, 54b.

[0051] Sensing of unwanted vibration at the fundamental in the y direction is accomplished with a bridge circuit. The emf induced by movement of the magnet 48 is separated and electronically enhanced by a frequency selective filter and used in a negative feedback loop. A monitor signal is also provided so that any mechanical dis-

turbance can be detected, even while the scanner is in operation.

[0052] It should be noted that magnet 48 is generally trapezoidal in shape both in the plane depicted in figure 2A and - to a lesser degree - in the plane perpendicular thereto, such that it tapers away from mount 44. This maximizes the angle through which fibre 42 (and hence magnet 48) can be deflected - from the equilibrium position shown in this figure - both in the plane of the figure and in the plane perpendicular to that plane, as constrained by avoiding contact with the coils and maximizing the volume of the magnet.

[0053] Thus, the motion of the magnet is maximized for the space provided, which is important for use in a small diameter endoscope. Similarly, the coils 50 are designed to minimize their volume for their desired strength. Figure 3 is a cross-sectional view of Y coils 54a, 54b and X coils 56a, 56b (within housing 46). All four coils are elliptical so that they impinge as little as possible on the space interior to the coils (in which the fibre 42 and magnet 48 must move) while maintaining the desired number of windings. The resulting ellipses each occupy one third of the housing diameter, leaving one third for the magnet 48 when in motion.

[0054] At maximum size the coils touch the housing 46 with equal curvature, and touch each other. The deflection of the magnet is calculated from elastic beam theory and the desired (or required) fibre tip deflection. The maximum magnet cross section that can be accommodated can then be determined. The benefit of using elliptical rather than circular coils is evident from figures 4A and 4B. Figure 4A depicts four circular coils 60 within a housing 62 (shown in cross-section), with a shaded interior space 64 left vacant for the fibre and magnet; such coils could be employed in scanner 40. Figure 4B, however, depicts the preferred arrangement of this embodiment, with four elliptical coils 66; shaded interior space 68 for the motion of the fibre and magnet is approximately twice the width and height of the space 64 of figure 4A. The additional internal space allows either a larger magnet or greater beam deflection - or both - than would be possible with circular coils.

[0055] Housing 46 - and hence scanner 40 - has a final overall diameter of ~4.5 and length of ~30 mm. Indeed, a scanner according to this embodiment with a diameter of 3.5 mm has been constructed. In addition, a version with a diameter of 3.0 mm and a length of 23 mm has been designed, and it is envisaged that still smaller versions could readily be constructed.

[0056] Figure 2B is a cross sectional side view of the scanner 40 at full Y deflection, that is, with fibre 42 deflected to its maximum extent in the Y direction. Scanner 40 is arranged to resonate at the first overtone in the X direction, however, as is illustrated schematically in figure 2C. A practical frequency range for mechanical resonant scanning is around 800 to 1000 Hz (or in some cases up to 1600 Hz) so, as mentioned above, scanner 40 is adapted to resonate at a first overtone of around 850 Hz. The

permanent magnet 48 is located close to the antinode for this mode, so the magnet does not move far (despite a greater tip deflection in the x direction than in the y direction) and, when moving, is not rotated relative to its rest alignment by as great an angle as is apparent in the Y scan shown in figure 2B. This has two consequences: little if any taper need be applied to the magnet 48 in the magnet's cross section that is apparent in figure 2C, and the size of that cross section can be maximized to take advantage to this minimal deflection.

[0057] The position of permanent magnet 48 along the fibre 42 is selected, in coarse terms, to provide sufficient scanning amplitude in the y direction (as the closer magnet 48 is to mount 44, the greater will be the scanning amplitude in the y direction), while providing adequate clearance in the x direction. This is then adjusted for optimum 1st overtone performance, and checked for compatibility with the requirement for low frequency alternating current Y deflection.

[0058] For a total fibre length of 18 mm the fundamental and first overtone frequencies have been computed and are plotted in figure 5 (as functions of the distance of the magnet 48 from the mount 44). The fundamental frequency 70 monotonically decreases as the distance of the magnet 48 from the mount 44. However, the overtone frequency 72 has a minimum at approximately 4 mm, which is in fact close to the position selected to provide a suitable Y deflection using a first overtone frequency of about 850 Hz. This position may be described as "optimum" in the sense that it employs the shortest fibre for this desired frequency, so minimizes the overall length of the scanner.

[0059] For a small diameter scanner (such as a long rigid scanner made to fit down a small diameter tube), where diameter is the over-riding consideration, the magnet would be positioned at the antinode to get parallel magnet motion and best clearance. However, if the scanner is for use in the rigid tip of a flexible endoscope (which are typically more useful if the rigid tip length is short), the aforementioned minimum frequency condition may be the preferred criterion, to provide the shortest scanner length for a given frequency of (overtone) operation. With practical clearances the magnet can be positioned between these two ideal positions; both are defined by parabolic minima so there would be very little sacrifice of performance. In this embodiment, magnet 48 is located at the minimum shown in figure 5, thus minimizing the length of the scanner, but this also places magnet 48 essentially at the vibration antinode so scanner diameter can also be minimized.

[0060] Figure 6 illustrates a sine/sawtooth pattern 80, as employed with scanner 40. Figure 6 is a cross sectional view through housing 62 at the position of the tip 82 of fibre 42. The tip 82 is shown in its four extreme deflections, with the tip 82 as close as possible to the housing 62 in each case to provide the largest possible image. Generally, only the central part 84 (shown with a solid curve) of the x direction sinusoidal deflection 80 -

and with tip 82 moving in one direction (such as left to right) - is used for data collection. However, the scanner 40 uses almost the entire vertical or y direction scan (which comprises essentially a linear sawtooth motion), amounting in practice to approximately half the x direction travel of the tip 82. This maintains an approximately square image. A greater portion of the x direction deflection may be used, if a greater degree of image distortion is acceptable or post-imaging processing is used to reduce that distortion.

[0061] Other scan patterns have been developed for those cases where the bimotional fibre cannot be sufficiently deflected except at resonance and advantage is taken of mechanical Q. This occurs when the available driving force is too small to deflect the fibre directly at low frequency when driven with an alternating current drive.

[0062] Another possible scan pattern for use with scanner 40 comprises a variable ellipse where the fibre touches the tube at only two points (i.e. the ends of ellipse).

In terms of speed, the area suitable for imaging when such a variable ellipse is used is slightly larger than with the pattern shown in figure 6. The Y amplitude of the elliptical pattern can be increased compared with that shown in figure 1D, but the mapping to a display then becomes more difficult; for some applications, however, those scan limits would be acceptable even with direct conversion to a rectilinear display.

[0063] A potential problem of scanner 40 - as it comprises a bimotional resonant cantilever - is that of whirling. Mount 44 is designed to provide a compliance that differs in the x and y directions; essentially straight line scanning can then be obtained with magnet 48 acted on by a single driving coil. Figure 7 is a schematic view of mount 44 (viewed along the z axis). Mount 44 includes a circular frame 90 with a thin transverse beam 92 that supports the base of the fibre 42. The transverse beam 92 can more readily twist to permit deflection in the y direction than it can warp to permit deflection in the x direction, so - as discussed above - compliance which is significantly different in the x and y directions.

[0064] Alternatively, a thin polymer strip (of, say, 0.1 mm thickness and 1 mm width) could be attached laterally to the fibre 42 in front of a substantially rigid mount.

This would also provide significantly different compliance in the x and y directions.

[0065] Whatever technique is employed, it is estimated that the compliance is sufficiently different if the difference - expressed in terms of frequency difference - is about 20 Hz (provided that the permanent magnet 48, when scanning in the x direction, does not come too close to the pole pieces of the Y coils 54a, 54b. As a low frequency alternating current Y drive is employed, this frequency difference can be made quite large without endangering the operation of scanner 40 in the y direction.

X ELECTRONICS

[0066] The X electronics of scanner 40 control the res-

onant scanning in the x direction, by sensing the x position of the magnet 48, controlling deflection at the overtone (with a positive feedback loop), suppressing vibration at the fundamental (with a negative feedback loop), and provides image synchronisation.

X Position Sensing

[0067] Figure 8 is a circuit diagram of the X electronics, which also depicts fibre 42 and magnet 48 between X drive coil 56a and X sensor coil 56b. As magnet 48 moves between the X coils, an emf is induced in X sensor coil 56b that is proportional to magnet velocity (rather than position), owing to magnet's motion relative to X sensor coil 56b. There will also be significant direct induction from the magnetic field of the X drive coil 56a into the X sensor coil 56b. More precisely, the mutual inductance will result in a signal proportional to the derivative of the drive current. It is easily measured off resonance and can be quantified.

[0068] Both of these effects - the induced emf and the direct induction - are annotated in the figure as two volt-

age generators (respectively $k_1 \frac{dx}{dt}$ and $L_m \frac{di}{dt}$) in

series at the back of the coil impedance. They pass (from the scanner 40) to a preamplifier and from there to an integrator. The output of the integrator is a position signal, but it is still contaminated by the direct induction, now proportional to the X drive current. This contaminant is removed by subtracting a portion of the drive current sampled as shown at the base of the X drive coil 56a. Finally, at the top right of the circuit diagram a signal is produced that is a good indicator of magnet position. There is a slight asymmetry in the nominally sinusoidal wave that is due to the geometry of the magnetic field, but it is of little consequence.

Deflection Control at the Overtone

[0069] A high pass filter in the positive feedback loop selects the overtone from the X sense signal (at the top right of the circuit diagram). Otherwise the fibre could start up at the fundamental at about 200 Hz. The signal path continues through the overtone select filter, via an all-pass phase shifter to a limiter. This limiter provides the non-linearity (needed in a positive feedback oscillator) to control amplitude. Above a certain fibre deflection amplitude, the limiter produces a signal limited to the supply rails. This constant amplitude signal is then attenuated appropriately at the input to the drive stage to give the desired scan. The drive waveform is therefore not strictly sinusoid but rather square owing to the limiter, which assists in adjusting the X sense signal to be free of contamination from the drive signal. If the drive signal were a sine wave the contamination would be less obvious. With a square wave drive, the compensation can be ad-

justed to eliminate the square wave addition to the X sense using an oscilloscope.

[0070] The role of scan amplitude control can be readily understood if ones imagines switching the system on with that control initially set to zero. If the gain is gradually increased, oscillation will start, producing a low level sine wave when the loop gain is unity. At this point the amplitude rises and falls markedly with the slightest change in the gain control with very slight amplitude regulation occurring with the build up of wind resistance and other level dependent losses. Advancing the control further will increase the amplitude at the limiter input so that clipping of the upper and lower peaks of the sine wave starts. At sufficiently high amplitude, the waveform at the input to the drive stage will approach the square wave referred to above.

Suppression of Vibration at the Fundamental

[0071] Some of the characteristics of the negative feedback loop used for vibration damping contrast sharply with the positive loop described above. For example, it aims to provide maximum possible loop gain, provide linearity, and emphasise the lower frequency region (particularly the fundamental mechanical resonance), without disturbing the oscillating loop but while maintaining a phase margin over the entire frequency range. The intended negative loop could easily turn positive outside the frequency range of interest.

[0072] It might be imagined that a single loop would suffice, with the phase characteristic adjusted over the two frequency ranges to act as a negative loop at low frequencies and a positive loop at high frequencies.

[0073] However, the non-linearity needed for amplitude control would cause cross-modulation of the signals in the drive to the X drive coil 56a. For that reason parallel loops are employed in this embodiment, which add after the limiter at the input to the drive stage.

[0074] Thus, commencing at the X sense signal, a peaked low pass filter selects the fundamental frequency range in a negative loop that has direct access to the drive stage, effectively bypassing the limiter used for amplitude control of the overtone. During scanning the loop gain can be adjusted for best results in terms of the interference to the image from external vibration. Alternatively the loop gain can be quantified by inserting a low amplitude probe signal into the drive stage and observing the signal returned at the filter output, which has passed through the entire system of X coils 56a, 56b and fibre 42. As the probe signal is tuned through the resonance band, amplitude and phase is measured relative to the probe. If the phase difference is close to 180° at peak response, the loop can be safely closed and vibration damping can be demonstrated.

Provision of Synchronising Signal for Imaging

[0075] A distinction should be drawn between scan-

ning versus imaging from a scan. Further, scanner 40 separately provides synchronising for image creation independent of excitation or return light being emitted by, or reflected back into, the fibre 42. In applications such as bar code scanning all required information can be picked up from the target, but for reliable endoscope imaging it is necessary to know the location of the tip of fibre 42 so that an image can be generated.

[0076] A virtue of confocal microscopy is that out-of-focus light is not admitted to the image. Operators often find that, on starting up a confocal microscope, the entire field of view is dark because the focal surface does not happen to intersect the object under view. Only as the depth is scanned (in the z direction) does any image information appear. For these reasons image-independent synchronising is essential for confocal microscopy.

[0077] Thus, returning to the top right of figure 8, the X sense signal is processed for zero crossing (centre of display) and the imaging equipment can display the scanned signal using appropriate delay.

[0078] At the start-up of the scanner 40 and its electronics, this X synchronising signal initiates the whole computer loop that provides the Y scan signal back to the scanner 40.

Y ELECTRONICS

[0079] Figure 9 is a circuit diagram of the Y electronics of scanner 40, which control the Y drive to move the fibre 42 and magnet 48 in the y direction. Both Y coils 54a, 54b carry drive current, for reasons of symmetry and to obtain adequate deflection of the magnet.

[0080] The force in the y direction acting on the magnet 48 has x components that are balanced. With only one Y coil in action, x would be modulated as the y scan proceeded, and at the extremes - where the magnet 48 approaches the poles of the Y coils - there would be the danger of the scan becoming elliptical. In addition, deflection in the y direction would not be as linear in terms of Y current.

[0081] There is another symmetry condition related to induction of the X drive field into the Y coils 54a, 54b. The X drive coil 56a is adjacent to, and almost in contact with, both Y coils 54a, 54b (as shown in figure 3). By connecting Y coils 54a, 54b in series as shown in figure 9, the induction of X into Y is largely cancelled.

[0082] The Y drive signal enters the Y electronics (from imaging equipment) at the upper left of figure 9; this signal is typically derived from a digital to analogue converter, and it is important to remove any components near the fundamental frequency. These can come from both the conversion and any sharp flyback of the sawtooth. Both are attenuated by a filter designed for a time domain response with no overshoot or ringing even for instantaneous retrace.

[0083] There remains the problem of ringing at the fundamental due to vibration in the external environment. Since there is no Y sense coil, the emf induced in the Y

coils 54a, 54b by the movement of the magnet 48 is used. This is done in the presence of the sawtooth drive in both Y coils.

[0084] A bridge is provided (to the left of the Y coils in the figure), which is used to cancel the drive signal and extract the voltage induced in both coils by magnet vibration in the y direction. The bridge output is amplified and passed through a bandpass filter, and added to the Y drive to quench the fundamental resonance in the Y direction.

TESTING

[0085] In addition to the potential perturbing effects discussed above, simple vibrational interference to the scan and the more subtle parametric modulation effect (where amplitude depends on mounting compliance) can present problems. The former arises from movement of the scanner during use (such as in an endoscope in vivo).

[0086] One may consider how the bending moment for scanning is supplied at the base of the cantilever fibre 42. The large moment required for the tine of a tuning fork scanner can only be provided by a balancing, preferably thicker, tine. By eliminating the fork entirely, the bending moment is reduced by an order of magnitude for a given deflection, as is the drive force also, and most importantly, the mechanical Q. The scanner 40 is thus less sensitive to mounting factors.

EXAMPLES

[0087] An X-only fibre cantilever was tested with a light weight mounting. The X sense signal was then measured under a variety of mounting conditions with constant drive. The amplitude varied by only a few percent, except for one case where clamping with pliers some distance from the base seemed to resonate together with the assembly. Merely touching the fibre mount region made the effect disappear.

[0088] Two scanners were then constructed, based on scanner 40, and incorporated into an endoscope. Several images were taken with these two scanners. Figure 10A is an image (reproduced in negative in figure 10B for clarity) of fluorescent fibres collected with the first of these scanners, and shows the effect of interference from vibration at the fundamental mechanical resonance. Although it appears as jitter in the x direction, it comes from very small glitches in the Y drive waveform. Similar effects could be produced with rapid retrace in the absence of careful filtering of the Y drive.

[0089] Figure 11 is an image of woven fibres collected with the second scanner, in which the jitter is absent in both X or Y directions and individual fibres can be seen showing fine detail.

[0090] Figure 12 is an image of a demanding target comprising a fluorescent grid at 12.5 micron spacing, and collected with the same scanner used to collect the image of figure 11. This gives an indication of the field of view

and linearity that can be achieved. The image has an approximately uniform scale over the entire field of view.

[0091] Figures 13A, 13B and 13C are views of an alternative fibre mount 100 (viz. alternative to mount 44), according to an embodiment of the present invention, for use with the scanner 40 of figure 2A. Fibre mount 100 - of wire cut titanium - comprises a generally semi-cylindrical base 102 (for locating in cylindrical housing 46 of scanner 40) and an integral forwardly directed cantilever 104 for holding an optical fibre 42, and joined to base 102 by neck 106. Base 102 has a diameter of approximately 3 mm. Cantilever 104 includes an upper groove 108 for receiving a portion of fibre 42, which then projects forwardly (i.e. in z direction) beyond cantilever 104 so that its forward end can be scanned essentially as illustrated in figures 2A to 2C. Base 102 is formed as less than a complete semi-cylinder to thereby locate groove 108 such that fibre 42 is coaxial with cylindrical housing 46. Fibre 42 is held in groove 108 with an adhesive. Groove 108 is longer (in the z direction) than the thickness (in the z direction) of mount 44, so fibre 42 can be more securely located in fibre mount 100 of this embodiment than in mount 44.

[0092] In addition, cantilever 104 acts somewhat like a springboard as it has a width in the lateral or x direction (of approximately 1 mm) that is significantly greater than its thickness in the vertical or y direction; it is thus stiffer and hence more resistant to displacement in the x direction than in the y direction. As a result, in an embodiment of scanner 40 with fibre mount 100, the resonance frequency for vibration of fibre 42 in the x direction was found to be 46 kHz greater than the resonance frequency for vibration of fibre 42 in the y direction, thereby facilitating a fast X scan and a slow Y scan.

[0093] Fibre mount 100 may optically include a generally cylindrical cut-out 112 in its lower periphery 114, to lighten mount 100 or to provide a feed-through to the forward portion of scanner 40 for electrical cables or the like.

[0094] Figures 14A, 14B and 14C are views of an alternative coil holder 120, according to an embodiment of the present invention, for use with the scanner 40 of figure 2A. Figure 14C depicts coil holder 120 provided with coils. Coil holder 120 - also of wire cut titanium - is generally cylindrical with a diameter of approximately 3 mm, and includes four identical and evenly spaced elliptical internal recesses 122 for accommodating four elliptical electromagnetic coils (shown at 124 in figure 14C) comparable to coils 50 of scanner 40. Unlike coils 50 of scanner 40, however, coils 124 are held by their outer windings rather than by their cores 126, through the engagement of their outer windings and the surfaces of respective recesses 122. Hence, coils 124 do not abut the interior wall of cylindrical housing 46, but rather abut the surfaces of recesses 122. Coil holder 120 allows precise and quick positioning of coils 124, and is inexpensive to manufacture.

[0095] In addition, one or more slots or grooves (not

shown) may optionally be provided in the external surface of coil holder 120 for engaging corresponding flanges provided on interior wall 52 of housing 46. These optional grooves and flanges would facilitate the positioning and securing in position of coil holder 120.

[0096] Figure 15 is an image of small intestine villi from a mouse, obtained with a confocal endoscope comprising an optical fibre scanner according to the embodiment of figure 2A though employing fibre mount 100 of figures 13A to 13C and coil holder 120 of figures 14A and 14B. The mouse was intravenously injected with 0.5 mL of a 1% solution of sodium fluorescein, and topical acriflavine (0.05% solution) was applied to the villi; the tissue was then imaged using 488 nm laser illumination.

[0097] Figure 16 is an image of liver vessels from a mouse, collected with the same apparatus as was the image of figure 15. The sample was prepared in the same manner as was that imaged in figure 15 (though without the application of topical acriflavine).

[0098] The field of view is approximately $500\ \mu\text{m} \times 500\ \mu\text{m}$ for the images of both figures 15 and 16.

[0099] Modifications within the scope of the invention may be readily effected by those skilled in the art. It is to be understood, therefore, that this invention is not limited to the particular embodiments described by way of example hereinabove.

[0100] In the claims that follow and in the preceding description of the invention, except where the context requires otherwise owing to express language or necessary implication, the word "comprise" or variations such as "comprises" or "comprising" is used in an inclusive sense, that is, to specify the presence of the stated features but not to preclude the presence or addition of further features in various embodiments of the invention.

Further, any reference herein to prior art is not intended to imply that such prior art forms or formed a part of the common general knowledge.

Claims

1. A method of scanning a light transmitter (42) having an exit tip (74, 82), comprising:

supporting said light transmitter (42) in a mount (44, 92, 100) located remotely from said exit tip (74, 82);

driving said light transmitter (42) to vibrate in a first direction (x) with a first driving force;

mounting said light transmitter (42) to have compliance in said first direction (x) that is significantly different from compliance in a second direction (y) orthogonal to said first direction (x);

driving said light transmitter (42) to vibrate in the second direction (y) with a second driving force; applying said first and second driving forces to said light transmitter (42) between said mount (44, 92, 100) and said exit tip (74, 82); and

synchronizing vibration of said light transmitter (42) in said first direction (x) with vibration of said light transmitter (42) in said second direction (y) so that the exit tip (74, 82) of the light transmitter (42) executes a scan pattern (80);

characterized in that said light emitter (42) is driven to vibrate resonantly in the first direction (x) with said first driving force; said light emitter (42) is driven to vibrate non-resonantly in the second direction (y) with said second driving force; and said scan pattern (80) approximates a rectilinear raster scan (80), with said light transmitter (42) executing sinusoidal vibration in said first direction (x) and linear vibration in said second direction (y).

2. A method as claimed in claim 1, including vibrating said light transmitter (42) in said first direction (x) at the first overtone of mechanical resonance.

3. A method as claimed in either claims 1 or 2, including:

driving said light transmitter (42) with an axially polarised magnet (48) mounted on said light transmitter (42), a first pair of axially oriented electromagnetic coils (56a, 56b) located on either side of the magnet (48) in the first direction (x) comprising a drive coil (56a) for driving said magnet (48) in said first direction (x) and a sensor coil (56b) for providing a signal for use in generating a position signal indicative of the position of the magnet (48) in the first direction (x), and a second pair of axially oriented electromagnetic coils (54a, 54b) located on either side of the magnet (48) in said second direction (y) for driving the magnet (48) in the second direction (y); and using said position signal to provide positive feedback to maintain light transmitter vibration in said first direction (x).

4. A method as claimed in claim 3, including using said position signal for synchronizing an image display.
5. A method as claimed in either claim 3 or 4, including deriving said position signal by integrating said output signal of said sensor coil (56b).
6. A method as claimed in any one of claims 3 to 5, including driving said drive coil (56a) with a drive current and subtracting a signal proportional to said drive current from said position signal to compensate for contamination of said position signal by a current induced in said sensor coil (56b) by the magnetic field of said drive coil (56a).
7. A method as claimed in any one of claims 3 to 6,

including employing additional coils for driving said light transmitter (42) in the first direction (x), said second direction (y), or in both said first direction (x) and said second direction (y).

5

8. A method as claimed in any one of claims 3 to 7, including locating said magnet (48) substantially at a vibration antinode so that said magnet (48) moves laterally without significant rotation; or substantially at a minimum in the overtone frequency versus magnet position curve (72) to minimize required light transmitter length.

10

15

9. A method as claimed in any one of claims 3 to 7, including locating said magnet (48) substantially at both a vibration antinode and a minimum in the overtone frequency versus magnet position curve (72).

20

10. A method as claimed in any one of claims 3 to 7, including vibrating said light transmitter (42) in said second direction (y) non-resonantly with low frequency alternating current excitation of said second pair of coils (54a, 54b).

25

11. A method as claimed in any one of claims 3 to 7, including vibrating said light transmitter (42) in said second direction (y) non-resonantly with varying direct current excitation of said second pair of coils (54a, 54b).

30

12. A method as claimed in claim 11, including providing a restorative force with a spring or with a resilience of said light transmitter (42).

35

13. A method as claimed in any one of the preceding claims, wherein said light transmitter (42) comprises an optical fibre or a plurality of optical fibres or an optical fibre bundle.

40

14. A method as claimed in any one of the preceding claims, including providing negative feedback at a fundamental frequency in both said first direction (x) and said second direction (y).

45

15. A method as claimed in any one of the preceding claims, including mounting said light transmitter (42) on a thin transverse beam (92).

50

16. A method as claimed in any one of the preceding claims, including mounting said light transmitter (42) on a cantilever (100) with a lower resonant frequency in one of said first and second directions (x, y) than in the other of said first and second directions (x, y).

55

17. A scanning apparatus, comprising:

a light transmitter (42) having an exit tip (74, 82);
a mount (44, 92, 100) for supporting said light

transmitter (42) and located remotely from said exit tip (74, 82);
 a drive (54a, 54b, 56a, 56b) for driving said light transmitter (42) to vibrate in a first direction (x) with a first driving force;
 wherein
 said mount (44; 92; 100) provides significantly different compliances in said first direction (x) and a second direction (y) orthogonal to said first direction (x);
 said drive (54a, 54b, 56a, 56b) drives said light transmitter (42) to vibrate in the second direction (y) with a second driving force;
 a synchronizer is provided for synchronizing vibration of said light transmitter (42) in said first direction (x) with vibration of said light transmitter (42) in said second direction (y) so that said exit tip of said light transmitter (42) executes a scan pattern (80); and
 said drive (54a, 54b, 56a, 56b) applies a driving force to said light transmitter (42) between said mount (44, 92, 100) and said exit tip (74; 82);
characterized in that said drive (54a, 54b; 56a, 56b) drives said light emitter (42) to vibrate resonantly in the first direction (x) with the first driving force and to vibrate non-resonantly in the second direction (y) with the second driving force; and said scan-pattern (80) approximates a rectilinear raster scan, with said light transmitter executing sinusoidal vibration in said first direction (x) and linear vibration in said second direction (y).

18. An apparatus as claimed in claim 17, wherein said drive comprises:

an axially polarised magnet (48) mounted on said light transmitter (42);
 a first pair of axially oriented electromagnetic coils (56a, 56b) located on either side of said magnet. (48) in said first direction (x) comprising a drive coil (56a) for driving said magnet (48) in said first direction (x) and a sensor coil (56b) for providing a signal for use in generating a position signal indicative of the position of said magnet (48) in said first direction (x); and
 a second pair of axially oriented electromagnetic coils (54a, 54b) located on either side of said magnet (48) in said second direction (y) for driving said magnet (48) in said second direction (y);
 wherein said position signal is suitable for providing feedback to maintain light transmitter vibration in said first direction (x).

19. An apparatus as claimed in claim 18, including an integrator for integrating an output signal of said sensor coil (56b) to generate said position signal.

20. An apparatus as claimed in either claim 18 or 19, configured to subtract a signal proportional to a drive current from said position signal to compensate for contamination of said position signal by a current induced in said sensor coil (56b) by the magnetic field of said drive coil (56a).

21. An apparatus as claimed in any one of claims 18 to 20, wherein said magnet (48) is located substantially at a vibration antinode so that said magnet (48) moves laterally without significant rotation, or substantially at a minimum in the overtone frequency versus magnet position curve (72), or substantially at both a vibration antinode and a minimum in said overtone frequency versus magnet position curve (72).

22. An apparatus as claimed in any one of claims 18 to 21, configured to vibrate said light transmitter (42) in said second direction (y) non-resonantly with low frequency alternating current excitation of said second pair of coils (54a, 54b).

23. An apparatus as claimed in any one of claims 18 to 22, further comprising a source of varying direct current for exciting said second pair of coils (54a, 54b) and thereby vibrate said light transmitter (42) in said second direction (y) non-resonantly.

24. An apparatus as claimed in any one of claims 17 to 23, further comprising a spring or other resilient mechanism for providing a restorative force to said light transmitter (42).

25. An apparatus as claimed in any one of claims 17 to 24, comprising an imaging system for processing return light from said light transmitter (42) and displaying an image generated therefrom.

26. An apparatus as claimed in any one of claims 17 to 25, wherein said apparatus (40) has a diameter of approximately 3.0 to 4.5 mm and a length of approximately 23 to 30 mm.

27. An imaging apparatus, comprising a scanning apparatus (40) as claimed in claim 17.

28. A microscope, an endoscope, an endomicroscope, an optical coherence tomograph, a confocal microscope, a confocal endoscope or a confocal multiphoton endoscope, comprising a scanning apparatus as claimed in claims 17.

Patentansprüche

1. Verfahren zum Scannen eines Lichtsenders (42) mit einer Ausgangsspitze (74, 82), umfassend:

- Halten des Lichtsenders (42) in einer Halterung (44, 92, 100), die von der Ausgangsspitze (74, 82) entfernt angeordnet ist;
 Antreiben des Lichtsenders (42) mit einer ersten Antriebskraft zum Schwingen in einer ersten Richtung (x);
 Anbringen des Lichtsenders (42) derart, dass er in der ersten Richtung (x) eine Nachgiebigkeit aufweist, die signifikant verschieden von der Nachgiebigkeit in einer zweiten Richtung (y) senkrecht zur ersten Richtung (x) ist;
 Antreiben des Lichtsenders (42) mit einer zweiten Antriebskraft zum Schwingen in der zweiten Richtung (y);
 Ausüben der ersten und der zweiten Antriebskraft auf den Lichtsender (42) zwischen der Halterung (44, 92, 100) und dem Ausgangsende (74, 82); und
 Synchronisieren der Schwingung des Lichtsenders (42) in der ersten Richtung (x) mit der Schwingung des Lichtsenders (42) in der zweiten Richtung (y), so dass die Ausgangsspitze (74, 82) des Lichtsenders (42) ein Scanmuster (80) ausführt;
dadurch gekennzeichnet, dass der Lichtsender (42) mit der ersten Antriebskraft derart angetrieben wird, dass er resonant in der ersten Richtung (x) schwingt;
 der Lichtsender (42) mit der zweiten Antriebskraft derart angetrieben wird, dass er nicht-resonant in der zweiten Richtung (y) schwingt; und
 sich das Scanmuster (80) einem geradlinigen Raster-Scan (80) annähert, wobei der Lichtsender (42) in der ersten Richtung (x) eine Sinusschwingung und in der zweiten Richtung (y) eine lineare Schwingung ausführt.
2. Verfahren nach Anspruch 1, umfassend ein Schwingen des Lichtsenders (42) in der ersten Richtung (x) beim ersten Oberton der mechanischen Resonanz.
 3. Verfahren nach einem der Ansprüche 1 oder 2, umfassend:
 - Antreiben des Lichtsenders (42) mit einem axial polarisierten Magneten (48), der an dem Lichtsender (42) angebracht ist, einem ersten Paar axial ausgerichteter elektromagnetischer Spulen (56a, 56b), die auf beiden Seiten des Magneten (48) in der ersten Richtung (x) angeordnet sind, umfassend eine Antriebsspule (56a) zum Antreiben des Magneten (48) in der ersten Richtung (x) und eine Senserspule (56b) zum Bereitstellen eines Signals zur Verwendung beim Erzeugen eines Positionssignals, das die Position des Magneten (48) in der ersten Richtung (x) angibt, und einem zweiten Paar axial ausgerichteter elektromagnetischer Spulen (54a, 54b), die auf beiden Seiten des Magneten (48) in der zweiten Richtung (y) zum Antreiben des Magneten (48) in der zweiten Richtung (y) angeordnet sind; und
 Verwenden des Positionssignals zum Bereitstellen einer positiven Rückkopplung, um die Lichtsenderschwingung in der ersten Richtung (x) aufrechtzuerhalten.
 4. Verfahren nach Anspruch 3, umfassend die Verwendung des Positionssignals zum Synchronisieren einer Bildanzeige.
 5. Verfahren nach Anspruch 3 oder 4, umfassend die Gewinnung des Positionssignals durch Integrieren des Ausgangssignals der Senserspule (56b).
 6. Verfahren nach einem der Ansprüche 3 bis 5, umfassend das Antreiben der Antriebsspule (56a) mit einem Antriebsstrom und das Subtrahieren eines zu dem Antriebsstrom proportionalen Signals von dem Positionssignal, um die Kontamination des Positionssignals durch einen Strom, der in der Senserspule (56b) durch das Magnetfeld der Antriebsspule (56a) induziert wird, zu kompensieren.
 7. Verfahren nach einem der Ansprüche 3 bis 6, umfassend die Verwendung zusätzlicher Spulen zum Antreiben des Lichtsenders (42) in der ersten Richtung (x), der zweiten Richtung (y) oder sowohl der ersten Richtung (x) und der zweiten Richtung (y).
 8. Verfahren nach einem der Ansprüche 3 bis 7, umfassend das Anordnen des Magneten (48) im Wesentlichen in einem Schwingungsbauch, so dass sich der Magnet (48) ohne signifikante Drehung lateral bewegt, oder im Wesentlichen in einem Minimum einer Kurve (72), in der die Obertonfrequenz gegen die Magnetposition aufgetragen ist, um die erforderliche Lichtsenderlänge zu minimieren.
 9. Verfahren nach einem der Ansprüche 3 bis 7, umfassend das Anordnen des Magneten (48) im Wesentlichen sowohl in einem Schwingungsbauch als auch in einem Minimum einer Kurve (72), in der die Obertonfrequenz gegen die Magnetposition aufgetragen ist.
 10. Verfahren nach einem der Ansprüche 3 bis 7, umfassend das nichtresonante Schwingen des Lichtsenders (42) in der zweiten Richtung (y) mit einer niederfrequenten Wechselstromanregung des zweiten Paares Spulen (54a, 54b).
 11. Verfahren nach einem der Ansprüche 3 bis 7, umfassend das nichtresonante Schwingen des Lichtsenders (42) in der zweiten Richtung (y) mit variierender Gleichstromanregung des zweiten Paares

Spulen (54a, 54b).

12. Verfahren nach Anspruch 11, umfassend das Bereitstellen einer Rückstellkraft mit einer Feder oder mit der Elastizität des Lichtsenders (42). 5
13. Verfahren nach einem der vorhergehenden Ansprüche, wobei der Lichtsenders (42) eine Lichtleitfaser oder mehrere Lichtleitfasern oder ein Lichtleitfaserbündel enthält. 10
14. Verfahren nach einem der vorhergehenden Ansprüche, umfassend das Bereitstellen einer negativen Rückkopplung bei einer Grundfrequenz sowohl in der ersten Richtung (x) als auch in der zweiten Richtung (y). 15
15. Verfahren nach einem der vorhergehenden Ansprüche, umfassend das Anbringen des Lichtsenders (42) an einem dünnen Querträger (92). 20
16. Verfahren nach einem der vorhergehenden Ansprüche, umfassend das Anbringen des Lichtsenders (42) an einem Ausleger (100) mit einer Resonanzfrequenz, die in der ersten oder der zweiten Richtung (x, y) tiefer als in der jeweils anderen Richtung (x, y) ist. 25
17. Scanvorrichtung, umfassend: 30
 - einen Lichtsender (42) mit einer Ausgangsspitze (74, 82);
 - eine Halterung (44, 92, 100), die zum Halten des Lichtsenders (42) bestimmt und von der Ausgangsspitze (74, 82) entfernt angeordnet ist; 35
 - einen Antrieb (54a, 54b, 56a, 56b) zum Antreiben des Lichtsenders (42) mit einer ersten Antriebskraft derart, dass dieser in einer ersten Richtung (x) schwingt; 40
 - wobei 45
 - die Halterung (44; 92; 100) in der ersten Richtung (x) und in einer zu der ersten Richtung (x) senkrechten Richtung (y) signifikant unterschiedliche Nachgiebigkeiten aufweist;
 - der Antrieb (54a, 54b, 56a, 56b) den Lichtsenders (42) mit einer zweiten Antriebskraft derart antreibt, dass dieser in der zweiten Richtung (y) schwingt;
 - ein Synchronisierer vorgesehen ist, um die Schwingung des Lichtsenders (42) in der ersten Richtung (x) mit der Schwingung des Lichtsenders (42) in der zweiten Richtung (y) so zu synchronisieren, dass die Ausgangsspitze des Lichtsenders (42) ein Scanmuster (80) ausführt; und 50
 - der Antrieb (54a, 54b, 56a, 56b) auf den Lichtsender (42) zwischen der Halterung (44, 92, 100) und der Ausgangsspitze (74; 82) eine An-

triebskraft ausübt;

dadurch gekennzeichnet, dass der Antrieb (54a, 54b; 56a, 56b) den Lichtsender (42) zum resonanten Schwingen in der ersten Richtung (x) mit der ersten Antriebskraft und zum nicht-resonanten Schwingen in der zweiten Richtung (y) mit der zweiten Antriebskraft antreibt; und sich das Scanmuster (80) einem geradlinigen Rasterscan annähert, wobei der Lichtsender in der ersten Richtung (x) eine Sinusschwingung und in der zweiten Richtung (y) eine lineare Schwingung ausführt.

18. Vorrichtung nach Anspruch 17, wobei der Antrieb umfasst:

einen axial polarisierten Magneten (48), der an dem Lichtsender (42) angebracht ist;
 ein erstes Paar axial ausgerichteter elektromagnetischer Spulen (56a, 56b), die auf beiden Seiten des Magneten (48) in der ersten Richtung (x) angeordnet sind, umfassend eine Antriebspule (56a) zum Antreiben des Magneten (48) in der ersten Richtung (x) und eine Sensorspule (56b) zum Bereitstellen eines Signals zur Verwendung beim Erzeugen eines Positionssignals, das die Position des Magneten (48) in der ersten Richtung (x) angibt; und
 ein zweites Paar axial ausgerichteter elektromagnetischer Spulen (54a, 54b), die auf beiden Seiten des Magneten (48) in der zweiten Richtung (y) zum Antreiben des Magneten (48) in der zweiten Richtung (y) angeordnet sind;
 wobei das Positionssignal geeignet ist, eine Rückkopplung bereitzustellen, um die Lichtsenderschwingung in der ersten Richtung (x) aufrechtzuerhalten.

19. Vorrichtung nach Anspruch 18, umfassend einen Integrator zum Integrieren eines Ausgangssignals der Sensorspule (56b), um ein Positionssignal zu erzeugen. 40
20. Vorrichtung nach Anspruch 18 oder 19, die ausgebildet ist, ein zu einem Antriebsstrom proportionales Signal von dem Positionssignal zu subtrahieren, um eine Kontamination des Positionssignals durch einen Strom, der in der Sensorspule (56b) durch das Magnetfeld der Antriebspule (56a) induziert wird, zu kompensieren. 45
21. Vorrichtung nach einem der Ansprüche 18 bis 20, wobei der Magnet (48) im Wesentlichen angeordnet ist in einem Schwingungsbauch, so dass sich der Magnet (48) ohne signifikante Drehung lateral bewegt, oder im Wesentlichen in einem Minimum einer Kurve (72), in der die Obertonfrequenz gegen die Magnetposition aufgetragen ist, oder im Wesentli-

chen sowohl in einem Schwingungsbauch als auch in einem Minimum der Kurve (72), in der Obertonfrequenz gegen die Magnetposition aufgetragen ist.

22. Vorrichtung nach einem der Ansprüche 18 bis 21, die ausgebildet ist, den Lichtsender (42) mit einer niederfrequenten Wechselstromanregung des zweiten Paares Spulen (54a, 54b) in der zweiten Richtung (γ) nicht-resonant schwingen zu lassen. 5
23. Vorrichtung nach einem der Ansprüche 18 bis 22, ferner umfassend eine Quelle zum Variieren eines Gleichstroms zur Anregung des zweiten Paares Spulen (54a, 54b), wodurch der Lichtsender (42) in der zweiten Richtung (γ) nicht-resonant schwingt. 10
24. Vorrichtung nach einem der Ansprüche 17 bis 23, ferner umfassend eine Feder oder einen anderen elastischen Mechanismus zum Versehen des Lichtsenders (42) mit einer Rückstellkraft. 15
25. Vorrichtung nach einem der Ansprüche 17 bis 24, umfassend ein Bildverarbeitungssystem zum Verarbeiten von Licht, das von dem Lichtsender (42) zurückkommt, und zum Anzeigen eines daraus erzeugten Bildes. 20
26. Vorrichtung nach einem der Ansprüche 17 bis 25, wobei die Einrichtung (40) einen Durchmesser von etwa 3,0 bis 4,5 mm und eine Länge von etwa 23 bis 30 mm hat. 25
27. Bildverarbeitungseinrichtung, umfassend eine Scanvorrichtung (40) nach Anspruch 17. 30
28. Mikroskop, Endoskop, Endomikroskop, optischer Kohärenztomograph, konfokales Mikroskop, konfokales Endoskop oder konfokales Multiphotonen-Endoskop, umfassend eine Scanvorrichtung nach Anspruch 17. 35

Revendications

1. Procédé de balayage d'un émetteur optique (42) muni d'un embout de sortie (74, 82), comprenant : 45
 - l'appui dudit émetteur optique (42) sur un support (44 ; 92 ; 100) situé à distance dudit embout de sortie (74 ; 82) ; 50
 - l'entraînement dudit émetteur optique (42) pour qu'il vibre dans une première direction (x) avec une première force d'entraînement ;
 - le support dudit émetteur optique (42) pour obtenir une élasticité dans ladite première direction (x), qui est significativement différente de l'élasticité dans une seconde direction (y), perpendiculaire à ladite première direction (x) ; 55

l'entraînement dudit émetteur optique (42) pour qu'il vibre dans la seconde direction (y) avec une seconde force d'entraînement ;
 l'application desdites première et seconde forces d'entraînement sur ledit émetteur optique (42) entre ledit support (44 ; 92 ; 100) et ledit embout de sortie (74 ; 82) ; et
 la synchronisation de la vibration dudit émetteur optique (42) dans ladite première direction (x) avec la vibration dudit émetteur optique (42) dans ladite seconde direction (y), de telle sorte que l'embout de sortie (74 ; 82) de l'émetteur optique (42) exécute un motif de balayage (80) ;
caractérisé en ce que ledit émetteur optique (42) est entraîné pour vibrer en résonance dans la première direction (x) avec ladite première force d'entraînement ;
 ledit émetteur optique (42) est entraîné pour qu'il vibre sans résonance dans la seconde direction (y) avec ladite seconde force d'entraînement ; et
 ledit motif de balayage (80) se rapproche d'un balayage de trame rectiligne (80), avec ledit émetteur optique (42) exécutant une vibration sinusoïdale dans ladite première direction (x) et une vibration linéaire dans ladite seconde direction (y).

2. Procédé selon la revendication 1, comprenant la mise en vibration dudit émetteur optique (42) dans ladite première direction (x) au niveau du premier pail de résonance mécanique.
3. Procédé selon l'une ou l'autre des revendications 1 ou 2, comprenant : 5

l'entraînement dudit émetteur optique (42) avec un aimant polarisé axialement (48) monté sur ledit émetteur optique (42), une première paire de bobines électromagnétiques orientées axialement (56a, 56b) placées de chaque côté de l'aimant (48) dans la première direction (x) comprenant une bobine d'entraînement (56a) pour entraîner ledit aimant (48) dans ladite première direction (x) et une bobine de détection (56b) pour fournir un signal destiné à être utilisé dans la génération d'un signal de position représentatif de la position de l'aimant (48) dans la première direction (x), et une seconde paire de bobines électromagnétiques orientées axialement (54a, 54b) placées de chaque côté de l'aimant (48) dans ladite seconde direction (y) pour entraîner l'aimant (48) dans la seconde direction (y) ; et
 l'utilisation dudit signal de position pour fournir un retour d'information positive afin de maintenir la vibration de l'émetteur optique dans ladite première direction (x).

4. Procédé selon la revendication 3, comprenant l'utilisation dudit signal de position pour synchroniser l'affichage d'une image.
5. Procédé selon l'une ou l'autre des revendications 3 ou 4, comprenant la dérivation dudit signal de position en intégrant ledit signal de sortie de ladite bobine de détection (56b).
6. Procédé selon l'une quelconque des revendications 3 à 5, comprenant l'entraînement de ladite bobine excitatrice (56a) par un courant d'excitation et la soustraction d'un signal proportionnel audit courant d'excitation dudit signal de position afin de compenser la contamination dudit signal de position par un courant induit dans ladite bobine de détection (56b) par le champ magnétique de ladite bobine excitatrice (56a).
7. Procédé selon l'une quelconque des revendications 3 à 6, comprenant l'emploi de bobines supplémentaires pour entraîner ledit émetteur optique (42) dans ladite première direction (x), ladite seconde direction (y), ou dans les deux dites première direction (x) et seconde direction (y).
8. Procédé selon l'une quelconque des revendications 3 à 7, comprenant la localisation dudit aimant (48) sensiblement au niveau d'un ventre de vibration de telle sorte que ledit aimant (48) se déplace latéralement sans rotation significative, ou sensiblement à un minimum sur la courbe de fréquence partielle/position de l'aimant (72) afin de réduire la longueur requise de l'émetteur optique.
9. Procédé selon l'une quelconque des revendications 3 à 7, comprenant la localisation dudit aimant (48) sensiblement à la fois au niveau d'un ventre de vibration et d'un minimum sur la courbe de fréquence partielle/position de l'aimant (72).
10. Procédé selon l'une quelconque des revendications 3 à 7, comprenant la mise en vibration dudit émetteur optique (42) dans ladite seconde direction (y) sans résonance avec une excitation par courant alternatif basse fréquence de ladite seconde paire de bobines (54a, 54b).
11. Procédé selon l'une quelconque des revendications 3 à 7 comprenant la mise en vibration dudit émetteur optique (42) dans ladite seconde direction (y) sans résonance avec une excitation variable par courant continu de ladite seconde paire de bobines (54a, 54b).
12. Procédé selon la revendication 11, comprenant la fourniture d'une force restauratrice à l'aide d'un ressort ou à l'aide d'un élément élastique dudit émetteur optique (42).
13. Procédé selon l'une quelconque des revendications précédentes, dans lequel ledit émetteur optique (42) comprend une fibre optique ou une pluralité de fibres optiques ou un faisceau de fibres optiques.
14. Procédé selon l'une quelconque des revendications précédentes, comprenant la fourniture d'un retour d'information négative à une fréquence fondamentale dans les deux dites première direction (x) et seconde direction (y).
15. Procédé selon l'une quelconque des revendications précédentes comprenant le montage dudit émetteur optique (42) sur une poutre transversale mince (92).
16. Procédé selon l'une quelconque des revendications précédentes comprenant le montage dudit émetteur optique (42) en porte-à-faux (100) avec une fréquence de résonance inférieure dans l'une desdites première et seconde directions (x, y) à celle de l'autre desdites première et seconde directions (x, y).
17. Appareil de balayage, comprenant :
 - un émetteur optique (42) muni d'un embout de sortie (74 ; 82) ;
 - un support (44 ; 92 ; 100) permettant de supporter ledit émetteur optique (42) et situé à distance dudit embout de sortie (74 ; 82) ;
 - un entraînement (54a, 54b, 56a, 56b) permettant d'entraîner ledit émetteur optique (42) pour qu'il vibre dans une première direction (x) avec une première force d'entraînement ;
 - dans lequel
 - ledit support (44) ; (92) ; (100) fournit des élasticités significativement différentes dans ladite première direction (x) et une seconde direction (y) perpendiculaire à ladite première direction (x) ;
 - ledit entraînement (54a, 54b, 56a, 56b) entraîne ledit émetteur optique (42) pour qu'il vibre dans la seconde direction (y) avec une seconde force d'entraînement ;
 - un synchroniseur permettant de synchroniser la vibration dudit émetteur optique (42) dans ladite première direction (x) avec la vibration dudit émetteur optique (42) dans ladite seconde direction (y), de telle sorte que ledit embout de sortie dudit émetteur optique (42) exécute un motif de balayage (80) ; et
 - dans lequel ledit entraînement (54a, 54b, 56a, 56b) applique une force d'entraînement au dit émetteur optique (42) entre ledit support (44 ; 92 ; 100) et ledit embout de sortie (74 ; 82) ;
 - caractérisé en ce que** ledit entraînement (54a, 54b, 56a, 56b) entraîne ledit émetteur optique

- (42) pour qu'il vibre en résonance dans la première direction (x) avec la première force d'entraînement et pour qu'il vibre sans résonance dans la seconde direction (y) avec la seconde force d'entraînement ; et ledit motif de balayage (80) se rapproche d'un balayage de trame rectiligne, avec ledit émetteur optique exécutant une vibration sinusoïdale dans ladite première direction (x) et une vibration linéaire dans ladite seconde direction (y).
18. Appareil selon la revendication 17, dans lequel ledit entraînement comprend :
- un aimant polarisé axialement (48) monté sur ledit émetteur optique (42) ;
 - une première paire de bobines électromagnétiques orientées axialement (56a, 56b) situées de chaque côté dudit aimant (48) dans ladite première direction (x) comprenant une bobine excitatrice (56a) permettant d'entraîner ledit aimant (48) dans ladite première direction (x) et une bobine de détection (56b) permettant de fournir un signal utilisé pour générer un signal de position indicatif de la position dudit aimant (48) dans ladite première direction (x) ; et
 - une seconde paire de bobines électromagnétiques orientées axialement (54a, 54b) situées de chaque côté dudit aimant (48) dans ladite seconde direction (y) permettant d'entraîner ledit aimant (48) dans ladite seconde direction (y) ; dans lequel ledit signal de position convient pour fournir un retour d'information afin de maintenir la vibration de l'émetteur optique dans ladite première direction (x).
19. Appareil selon la revendication 18, comprenant un intégrateur permettant d'intégrer un signal de sortie de ladite bobine de détection (56b) afin de générer ledit signal de position.
20. Appareil selon l'une ou l'autre des revendications 18 ou 19, configuré pour soustraire un signal proportionnel à un courant d'excitation dudit signal de position afin de compenser la contamination dudit signal de position par un courant induit dans ladite bobine de détection (56b) par le champ magnétique de ladite bobine excitatrice (56a).
21. Appareil selon l'une quelconque des revendications 18 à 20, dans lequel ledit aimant (48) est situé sensiblement au niveau d'un ventre de vibration de telle sorte que ledit aimant (48) se déplace latéralement sans rotation significative, ou sensiblement à un minimum sur la courbe de fréquence partielle en fonction de la position de l'aimant (72), ou sensiblement à la fois au niveau d'un ventre de vibration et d'un minimum sur la courbe de fréquence partielle en fonction de la position de l'aimant (72).
22. Appareil selon l'une quelconque des revendications 18 à 21, configuré pour faire vibrer ledit émetteur optique (42) dans ladite seconde direction (y) sans résonance avec une excitation par courant alternatif basse fréquence de ladite seconde paire de bobines (54a, 54b).
23. Appareil selon l'une quelconque des revendications 18 à 22, comprenant en outre une source de courant continu variable pour exciter ladite seconde paire de bobines (54a, 54b), et de fait faire vibrer ledit émetteur optique (42) dans ladite seconde direction (y) sans résonance.
24. Appareil selon l'une quelconque des revendications 17 à 23, comprenant en outre un ressort ou un autre mécanisme élastique pour fournir une force restauratrice audit émetteur optique (42).
25. Appareil selon l'une quelconque des revendications 17 à 24, comprenant un système d'imagerie pour traiter un signal de réponse dudit émetteur optique (42) et afficher une image générée par celui-ci.
26. Appareil selon l'une quelconque des revendications 17 à 27, dans lequel ledit appareil (40) présente un diamètre égal à environ 3,0 à 4,5 mm et une longueur égale à environ 23 à 30 mm.
27. Appareil d'imagerie, comprenant un appareil de balayage (40), selon la revendication 17.
28. Microscope, endoscope, endomicroscope, tomographe par cohérence optique, microscope confocal, endoscope confocal, endoscope multiphoton confocal, comprenant un appareil de balayage selon la revendication 17.

摘要(译)

一种扫描装置 (40) 和方法 , 该装置包括光发射器 (42) , 用于支撑远离其出射尖端的光发射器 (42) 的底座 (44) , 用于驱动光发射器 (42) 的驱动器在第一方向 (X) 上共振振动并在与第一方向垂直的第二方向 (Y) 上非共振地振动 , 以及用于使光发射器在第一 (X) 和第二 (Y) 方向上振动同步的同步器因此光发射器 (42) 的出口尖端执行扫描模式。驱动器向安装件和出口尖端之间的光发射器施加驱动力。

$$k_1 \frac{dx}{dt}$$
