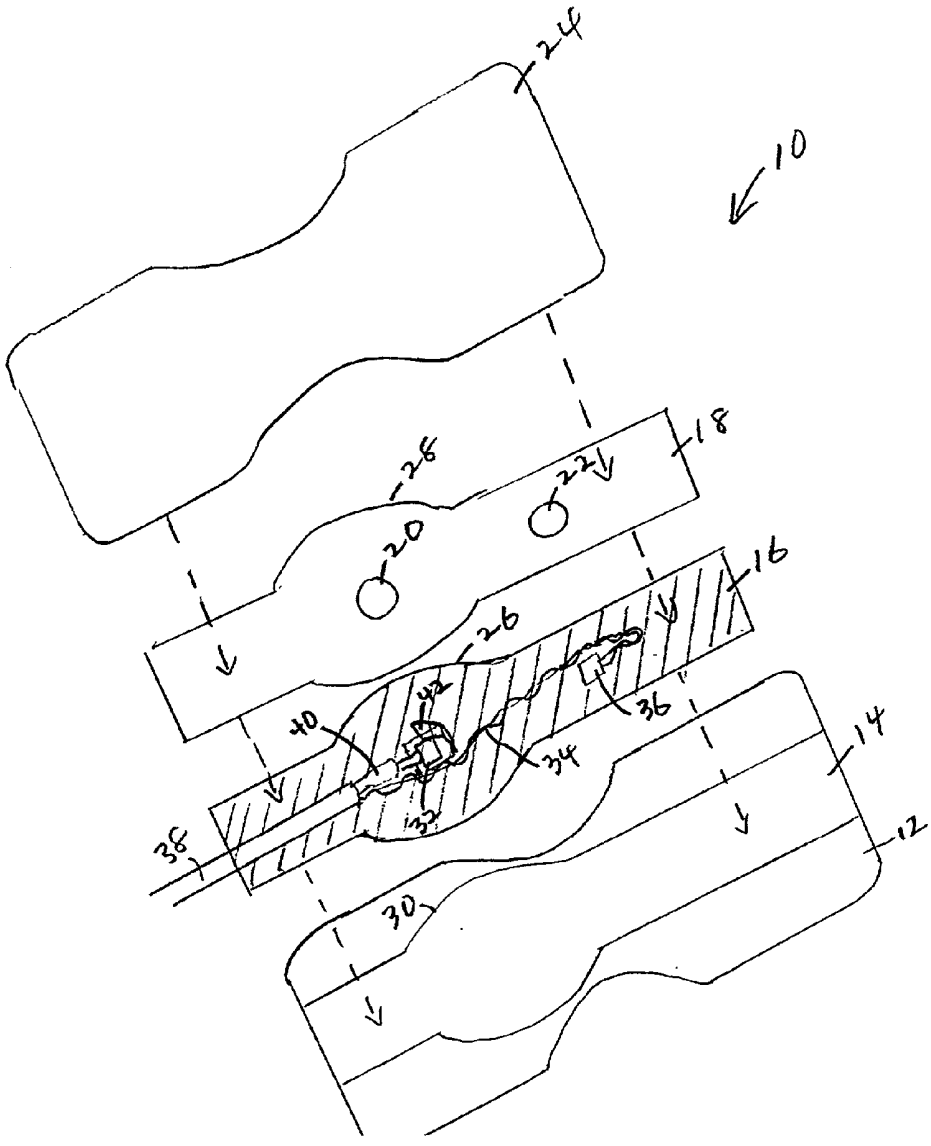
(57) **ABSTRACT**

A pulse oximeter sensor having an opaque, metalized layer to shield from ambient light. The metalized layer surrounds the area of the light detector. In one embodiment, the sensor has a transparent portion, with the opaque, metalized layer covering only the portions around the light detector and other areas, such as a strip extending between the light detector and the emitter. In a preferred embodiment, the opaque, metalized layer is a strip which has a widened portion in the area around the light detector.



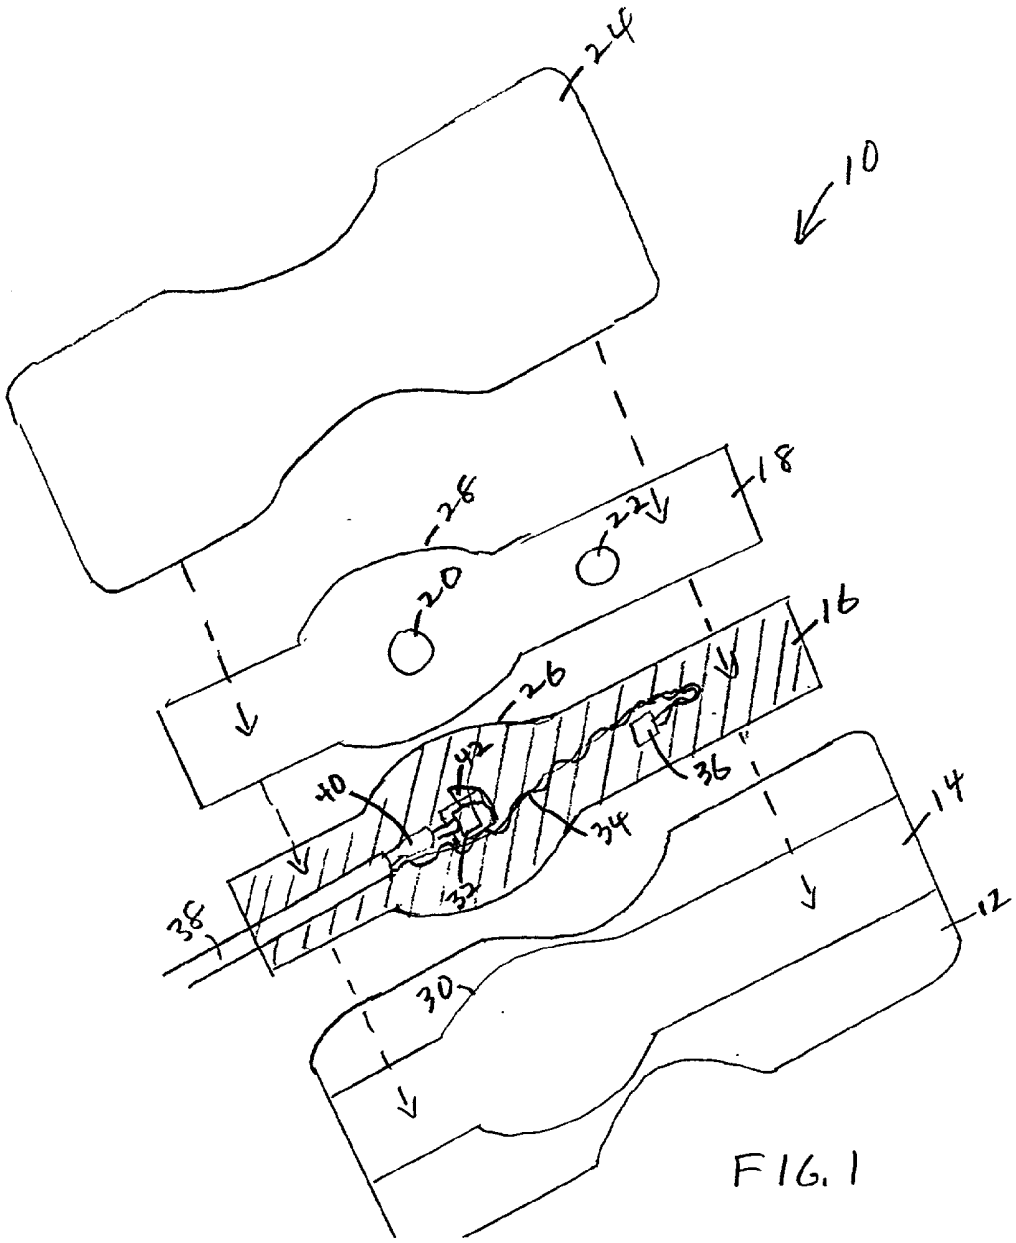


FIG. 1

PULSE OXIMETER SENSOR WITH WIDENED METAL STRIP

BACKGROUND OF THE INVENTION

[0001] The present invention relates to pulse oximeter sensors, and in particular to techniques for shielding against ambient light and preventing delamination of flexible, disposable sensors.

[0002] A type of pulse oximeter sensor that is commonly used is a flexible, disposable sensor. It typically has multiple layers, with white layers on the outside visible to the user. The white gives the image of cleanliness and sterility, and also is opaque to certain wavelengths of light over the range of the photodetector's sensitivity. An example of a sensor referring to a white opaque layer is set forth in U.S. Pat. No. 4,865,038.

[0003] A number of these sensors include metalized layers which can be either a conductive shield or a shield from ambient light. See, for example, U.S. Pat. Nos. 4,928,691; 5,246,003; 5,094,240; 5,054,488; and 4,964,408. U.S. Pat. No. 4,928,691 refers to the use of a red layer to avoid ambient light.

[0004] Ambient light can interfere with the operation of a pulse oximeter, especially under the bright lights of surgery or in outdoor, daylight conditions. While the use of a metal layer has been effective to shield from such ambient light, there is also a competing desire to have transparency in order to observe how a sensor is attached. In addition, the introduction of additional layers into the sensor is susceptible to sensor failure by delamination.

[0005] Accordingly, it would be desirable to have a sensor which would shield against ambient light, be resistant to delamination and have some transparency.

SUMMARY OF THE INVENTION

[0006] The present invention provides a pulse oximeter sensor having an opaque, metalized layer to shield from ambient light. The metalized layer surrounds the area of the light detector. In one embodiment, the sensor has a transparent portion, with the opaque, metalized layer covering only the portions around the light detector and other areas, such as a strip extending between the light detector and the emitter. In a preferred embodiment, the opaque, metalized layer is a strip which has a widened portion in the area around the light detector.

[0007] The widened portion of the metalized layer, in conjunction with widened portions that match on adjacent layers, resists delamination stresses.

[0008] In another aspect of the invention, the wires connecting to the emitter take an angular path, preferably crossing over from one side of the detector, across a center line between the emitter and detector, to an opposite side of the emitter. This angular path, as opposed to a straight path, disperses stresses caused by the wires, further inhibiting delamination or separation of the layers of the sensor.

[0009] In a preferred embodiment, the widened area of the metalized and adjacent layers has a semi-circular profile around the photodetector.

[0010] For a further understanding of the nature and advantages of the invention, reference should be made to the following description taken in conjunction with the accompanying drawing.

BRIEF DESCRIPTION OF THE DRAWINGS

[0011] **FIG. 1** is an exploded view of a sensor according to the present invention showing the different layers.

DESCRIPTION OF THE SPECIFIC EMBODIMENTS

[0012] **FIG. 1** illustrates a sensor **10** according to the invention. The sensor includes a transparent layer **12** which is wider than a white layer **14** mounted on top of it. On top of white layer **14**, is mounted a correspondingly-shaped metalized layer **16**. On metalized layer **16** is mounted another white layer **18** having holes **20** and **22** allowing light to pass from/to the emitter and detector. The emitter and detector are mounted on metalized layer **16**. Adhesives may be used between the layers for mounting.

[0013] As can be seen, metalized layer **16** includes a widened region defined by a curved perimeter **26**. Similar widened regions **28** and **30** are found on white strips **18** and **14**, respectively. This widened area surrounds the photodetector **32**. Such a widened area prevents ambient light from reaching the photodetector and disturbing its readings. At the same time, by only widening a portion of the strip, other areas of transparent layer **12** allow viewing of the patient when the sensor is attached. This allows, for example, an examination of how tightly the sensor is secured to the patient by looking through transparent layer **12**.

[0014] Widened area **26** and corresponding widened areas **28** and **30** also resist delamination. As opposed to a straight line strip, these areas are curved such that when the sensor is wrapped around a user's finger or other appendage, the stresses are dispersed rather than being focused on a line. Accordingly, it has been found that this design resists delamination and has fewer failures than a straight strip.

[0015] Another stress that can result in delamination is the stress induced by the wires **34** which connect to the emitter or light emitting diode (LED) **36**. The present invention reduces the stresses by providing an angular path of wires **34** between cable **38** and photo emitter or LEDs **36**. In prior devices, the wires were laid out in a straight line, which was found to contribute to delamination. The angular path where the wires start out beside photodetector **32** and cross the center line between the photodetector and emitter, then above emitter **36** reduces the stresses.

[0016] In addition, the wires circle around and attach to photo emitter **36** from the backside, as in previous devices. Also, as in previous devices, photodetector **32**, which attached to a coaxial cable **40** inside cable **38**, is mounted closer to cable **38** so that the coaxial cable extends onto less of the sensor.

[0017] Preferably, metalized layer **16** is a layer of aluminized mylar having a thickness of less than 1 mm. The curved area **26** preferably extends for at least three-quarters of an inch, more preferably slightly more than one inch along the length of strip **16**. It preferably extends outward from the straight edge of strip **16** by at least one-eighth of an inch, more preferably approximately one-quarter inch.

[0018] **FIG. 1** also shows a Faraday shield **42** which wraps around photodetector **32**. It is shown partially open in **FIG. 1**. The Faraday shield is preferably a piece of copper which is solid metal, except for a mesh portion directly above

photodetector **32**. In one embodiment, part of Faraday shield **42** attaches directly to metal layer **16**.

[**0019**] As will be understood by those of skill in the art, the present invention may be embodied in other specific forms without departing from the essential characteristics thereof. For example, the widened area could be any shape, not just semi-circular. It could be more of an oval shape, square, trapezoidal, etc. Additionally, the metalized layer need not extend the entire length of the sensor, but could simply be in the area around the photodetector, or around the photodetector and photo emitter. Additionally, wires **34** could take any other angular path between the emitter and detector. Also, the strips themselves could be other shapes, with the transparent strip **12** in particular having other patterns for the portion which is viewable. Parts (layers) may have translucent layered components as well as transparent layered components. Layer **16** could be a metalized translucent layer. Layer **12** can be transparent. Layer **18** can be reflective white layer. Layer **24** is not used in a preferred embodiment. Layer **24** can be added if delamination is a problem. In one embodiment there are adhesive layers between each of layers **12**, **1416**, and **18**.

[**0020**] Accordingly, the foregoing description is intended to be illustrative, but not limiting, of the scope of the invention which is set forth in the following claims.

What is claimed is:

1. A pulse oximeter sensor comprising:

a flexible, transparent substrate;

an opaque, metalized layer mounted on a first side of said transparent substrate, said metalized layer covering only a portion of said transparent substrate;

a light emitter mounted on a first side of said metalized layer to emit light away from said metalized layer;

a light detector mounted on said first side of said metalized layer;

a non-transparent layer mounted over said light emitter and said detector, said non-transparent layer having holes over said light emitter and detector; and

an adhesive layer disposed on said non-transparent layer and a portion of said transparent layer not covered by said metalized layer and said non-transparent layer.

2. The sensor of claim 1 further comprising a second flexible, non-transparent layer mounted between said transparent layer and said metalized layer.

3. The sensor of claim 1 wherein said metalized layer comprises a strip extending at least from said emitter to said detector, said strip having a wider portion adjacent said detector.

4. The sensor of claim 3 wherein said wider portion of said strip has a curved perimeter.

5. The sensor of claim 4 wherein said curved perimeter extends along at least three quarters of an inch on both sides of said strip adjacent said detector, and extends outward at least an eighth of an inch from said strip at a maximum point of extension.

6. The sensor of claim 3 wherein said non-transparent layer comprises a strip having a wider portion matching said wider portion of said metalized layer.

7. The sensor of claim 1 further comprising a cable extending into said sensor, said detector being mounted closer to said cable than said emitter, and further comprising wires from said cable connecting to said emitter, said wires crossing over a line between said emitter and said detector in a region between said emitter and said detector.

8. The sensor of claim 1 further comprising a Faraday shield at least partially surrounding said detector, said Faraday shield being connected to said metalized layer.

9. A pulse oximeter sensor comprising:

a flexible, transparent substrate;

an opaque, metalized layer mounted on a first side of said transparent substrate, said metalized layer covering only a portion of said transparent substrate, said metalized layer being a strip extending at least from said emitter to said detector, said strip having a wider portion adjacent said detector, said wider portion of said strip having a curved perimeter;

a light emitter mounted on a first side of said metalized layer to emit light away from said metalized layer;

a light detector mounted on said first side of said metalized layer;

a first non-transparent layer mounted over said light emitter and said detector, said non-transparent layer having holes over said light emitter and detector;

a second flexible, non-transparent layer mounted between said transparent layer and said metalized layer; and

an adhesive layer disposed on said non-transparent layer and a portion of said transparent layer not covered by said metalized layer and said non-transparent layer.

10. The sensor of claim 9 wherein said curved perimeter extends along at least three quarters of an inch on both sides of said strip adjacent said detector, and extends outward at least an eighth of an inch from said strip at a maximum point of extension.

11. The sensor of claim 9 further comprising a cable extending into said sensor, said detector being mounted closer to said cable than said emitter, and further comprising wires from said cable connecting to said emitter, said wires crossing over a line between said emitter and said detector in a region between said emitter and said detector.

12. The sensor of claim 9 further comprising a Faraday shield at least partially surrounding said detector, said Faraday shield being connected to said metalized layer.

13. A pulse oximeter sensor comprising:

a first non-transparent strip having a wider portion, said wider portion having a curved perimeter;

a light emitter mounted on a first side of said first non-transparent strip to emit light away from said first non-transparent strip;

a light detector mounted on said first side of said first non-transparent strip adjacent said wider portion of said first non-transparent strip;

said first non-transparent strip extending at least from said emitter to said detector;

a second non-transparent strip mounted over said light emitter and said detector, said second non-transparent strip having holes over said light emitter and detector,

said second non-transparent strip having a wider portion matching the shape of said wider portion of said first non-transparent strip;

an adhesive layer disposed on said second non-transparent strip.

14. The sensor of claim 13 further comprising:

a flexible, transparent substrate mounted on an outside of said first non-transparent strip opposite said emitter and detector, said transparent substrate having a portion extending beyond said first non-transparent strip, and said adhesive layer also being disposed on a said portion of said transparent layer extending beyond said first non-transparent layer.

15. The sensor of claim 13 further comprising a cable extending into said sensor, said detector being mounted closer to said cable than said emitter, and further comprising wires from said cable connecting to said emitter, said wires crossing over a line between said emitter and said detector in a region between said emitter and said detector.
