(73) Assignee: **REMON MEDICAL TECHNOLOGIES LTD.**, Caesarea (IL)

Sensing devices and methods of implanting sensing devices within an anatomical vessel network of a patient are provided. In one method, a fixation element (e.g., a stent or coil) of the sensing device is expanded into firm contact with a wall of a main anatomical vessel (e.g., a right pulmonary artery), and a stabilization element of the sensing device is placed into contact with a wall of an anatomical vessel branch of the main anatomical vessel. In another method, a first fixation element of the sensing device is expanded into firm contact with the wall of the main anatomical vessel (e.g., a right pulmonary artery) at a longitudinal location proximal to the anatomical vessel branch, and a second fixation element of the sensing device is expanded into firm contact with the wall of the main anatomical vessel at a longitudinal location distal to the anatomical vessel branch.

## DEVICES FOR FIXING A SENSOR IN A LUMEN

### RELATED APPLICATIONS

[0001] The application claims priority from U.S. Provisional Patent Application Ser. No. 60/737,131, filed Nov. 15, 2005, and is a continuation-in-part of U.S. patent application Ser. No. 11/034,502, filed Jan. 12, 2005, both of which are expressly incorporated herein by reference.

### FIELD OF THE INVENTION

[0002] The invention relates to the field of implantable medical devices, and in particular, to devices and methods for positioning a sensor within the lumen of a blood vessel.

### BACKGROUND OF THE INVENTION

[0003] The use of sensing devices in anatomical lumens is well known. For example, U.S. Pat. No. 4,485,813 describes a cardiac pacemaker sensor that can be permanently implanted in a specific location within a patient's body. U.S. Pat. Nos. 6,645,143, 6,053,873, and 6,442,413 and U.S. Patent Publication No. 2002/0188207 describe medical monitoring sensors designed to be permanently implanted in blood vessels and capable of sensing and transmitting via a telemetry link to an external monitor. The implanted sensing devices are utilized for monitoring physiological parameters within the patient's body.

[0004] Because the force created by the blood flow and/or heart movement, which may act on an implanted sensing device like a sail, tends to drag the sensing device longitudinally along the vessel, or rotate it in the case where the sensing device is implanted adjacent a bifurcation of a vessel branch, it is critical that the anchoring force created between the sensing device and the wall of the blood vessel be as great as possible. However, high local or radial force on the relative weak pulmonary artery vessel wall may cause perforation or aneurysm. Many of the vascular implantation techniques assume that the segment of the blood vessel in which the sensing device is intended to be implanted is straight (i.e., it has no branches). In some cases, however, the vessel segment may be branched. If the vessel segment adjacent the branch is long enough to accommodate the entire length of the sensing device, the sensing device may be implanted within the blood vessel without regard to the branch. If, however, the length of the vessel segment is limited, the sensing device may not be adequately implanted within the vessel segment without crossing the branch. In this case, the implanted sensing device may block future access to the vessel branch, e.g., during catheterization, may be unstable due to the transverse blood flow through the branch, and worse yet, may cause blood clots that may potentially result in an embolism. As a result, the length of the sensing device sufficient for affixation to the wall of the blood vessel may have to be reduced in order to accommodate the branched vessel. In addition, the diameters of many blood vessels are not uniform, and may even be conical, thereby presenting further challenges to lengthening the sensing device.

[0005] The right pulmonary artery, which is frequently the target of sensor implantation, such as for the purpose of monitoring hemodynamic parameters indicative of the efficiency of the heart or measure the glucose level of the blood, is both branched and non-uniform. For example, referring to

FIG. 1, an implantable sensing device 10, which generally includes a fixation element 12 (e.g., a stent) and a sensing element 14 coupled to the fixation element 12, is shown implanted within the right pulmonary artery RPA of a patient. As shown by the arrows, blood flows from the right ventricle RV of the heart, out through the main pulmonary artery MPA, which branches into the right pulmonary artery RPA and a left pulmonary artery LPA. The sensing element 14, once implanted, may thus be capable of monitoring, e.g., the hemodynamic parameters of the blood flowing from the right ventricle RV.

[0006] As can be seen in FIG. 1, the right pulmonary artery RPA branches into various side branches SBR, none of which is crossed by the sensing device 10 to prevent the afore-mentioned problems from occurring. However, because the length of the implantable segment of the right pulmonary artery RPA (i.e., the segment between the point at which the right pulmonary artery RPA begins and the point at which the first side branch SBR, known anatomically as "Truncus anterior", begins) is relatively short (on average, about 40 mm), the length of the fixation element 12 must be relative short in order to accommodate the side branch SBR.

[0007] Because the length of the fixation element 12 must be relatively short, the stability of the sensing device 10 may be compromised. In addition, as can be seen from FIG. 1, the diameter of the right pulmonary artery RPA substantially decreases in the distal direction (i.e., from right to left), which causes the proximal end of the fixation element 12 to engage the vessel wall less firmly than the distal end of the fixation element 12 engages the vessel wall, thereby further compromising the stability of the sensing device 10.

[0008] There, thus, is a need to provide an improved technique for implanting a sensing device in a non-uniform and branched anatomical vessel.

### SUMMARY OF THE INVENTION

[0009] In accordance with a first aspect of the present inventions, an implant for sensing parameters within an anatomical vessel network (e.g., the blood vessel network) of a patient is provided. The implant comprises a first fixation element having an expanded geometry for firmly engaging a wall of the vessel network at a first longitudinal location, and a second fixation element having an expanded geometry for firmly engaging the wall of vessel network at a second longitudinal location. The fixation elements can take the form of any suitable element, such as, e.g., a stent or a coil. The first and second longitudinal locations may be, e.g., in a single anatomical vessel, or respectively in a main anatomical vessel and an anatomical vessel branch of the main anatomical vessel. In one method, the vessel network has substantially differing diameters at the first and second longitudinal locations.

[0010] The implant further comprises a connecting element mechanically coupling the first and second fixation elements together in an articulating manner. The implant can optionally comprise a third fixation element having an expanded geometry for firmly engaging the wall of vessel network at a third longitudinal location, and another connecting element mechanically coupling the second and third fixation elements together in an articulating manner. While the present inventions should not be so limited in their

broadest aspects, articulation of the fixation elements allows them to expand and move relative to each other, so that, e.g., they can be implanted within misaligned vessel segments (e.g., a main anatomical vessel and a branch of the anatomical vessel) or vessel segments with non-uniform diameters.

[0011] The implant further comprises a sensing element mechanically coupled to the first fixation element opposite the connecting element. The sensing element can be, e.g., one or more of a pressure sensor, an accelerometer, a position sensor, a wall motion sensor, a flow sensor, a temperature sensor, an oxygen sensor, a calcium sensor, a potassium sensor, a glucose sensor, a coagulation sensor, an electrical activity sensor, and a pH sensor. In an optional embodiment, the implant further comprises a transmitter configured for wirelessly transmitting information sensed by the sensing element to a remote receiver.

[0012] In accordance with a second aspect of the present inventions, a method of implanting a sensing device within an anatomical vessel network (e.g., a blood vessel network) of a patient is provided. The method comprises expanding a fixation element (e.g., a stent or coil) of the device into firm contact with a wall of a main anatomical vessel (e.g., a right pulmonary artery), and locating a stabilization element of the device into contact with a wall of an anatomical vessel branch of the main anatomical vessel. By way of non-limiting example, the stabilization element may be a second fixation element that is expanded into firm contact with the wall of the anatomical vessel branch or an element that resists rotation of the fixation element about a longitudinal axis of the main anatomical vessel. An optional method comprises expanding a third fixation element of the device into firm contact with the wall of the main anatomical vessel, wherein the first fixation element is located proximal to the anatomical vessel branch, and the third fixation element is located distal to the anatomical vessel branch. Optionally, the distal and/or proximal anchor may have hooks for adding active fixation of the device minimizing potential migration.

[0013] In accordance with a third aspect of the present inventions, a method of implanting a sensing device within an anatomical vessel network (e.g., a blood vessel network) having a main anatomical vessel and an anatomical vessel branch of the main anatomical vessel is provided. The method comprises expanding a first fixation element of the device into firm contact with the wall of the main anatomical vessel (e.g., a right pulmonary artery) at a longitudinal location proximal to the anatomical vessel branch, and expanding a second fixation element of the device into firm contact with the wall of the main anatomical vessel at a longitudinal location distal to the anatomical vessel branch. The fixation elements can take the form of any suitable element, such as a stent or a coil. An optional method comprises expanding a third fixation element of the device into firm contact with the wall of the anatomical vessel branch.

[0014] The methods described above may optionally comprise locating a sensing element of the sensing device within the main anatomical vessel when the first fixation element is firmly engaged with the wall of the main anatomical vessel and the stabilization element is in contact with the wall of the anatomical vessel branch. The sensing element may be operated to measure, e.g., one or more of a pressure, acceleration, wall motion, fluid flow, temperature, oxygen

level, glucose level, coagulation, electrical activity, and pH level within the anatomical vessel. Such measured information can be wirelessly transmitted from the sensing device.

[0015] While the present inventions should not be so limited in their broadest aspects, in accordance with the afore-described methods, the only portion of the sensing device within the bifurcation between the main anatomical vessel and the anatomical branch is the connecting element, which may have a relatively low profile. As a result, very little force will be applied to the sensing device by fluid flowing between the anatomical branch and the main anatomical vessel, thereby increasing the stability of the sensing device within the main anatomical vessel, and in the case where the fluid is blood, decreasing the chance of embolism that may otherwise result from clots formed by the obstructed blood flow. In addition, because the connecting element may have a low profile, future access to the anatomical branch is not significantly hindered, thereby preserving the capability of catheterizing the anatomical branch if necessary or desired. The connecting element allows the fixation elements to follow the anatomical vessel shape and movement, while preventing device migration. Also, the connecting elements enable a long, yet flexible, sensing device, thereby allowing easy delivery even through tortuous vessels, while its length prevents it from rotating into a bifurcation.

[0016] Other and further aspects and features of the invention will be evident from reading the following detailed description of the preferred embodiments, which are intended to illustrate, not limit, the invention.

#### BRIEF DESCRIPTION OF THE DRAWINGS

[0017] The drawings illustrate the design and utility of preferred embodiments of the present invention, in which similar elements are referred to by common reference numerals. In order to better appreciate how the above-recited and other advantages of the present inventions are obtained, a more particular description of the present inventions briefly described above will be rendered by reference to specific embodiments thereof, which are illustrated in the accompanying drawings. Understanding that these drawings depict only typical embodiments of the invention and are not therefore to be considered limiting of its scope, the invention will be described and explained with additional specificity and detail through the use of the accompanying drawings in which:

[0018] FIG. 1 is a side view of a prior art sensing device arrangement within a pulmonary arterial network of a patient;

[0019] FIG. 2 is a side view of a first sensing device arrangement within the pulmonary arterial network in accordance with the present inventions;

[0020] FIG. 3 is a side view of a second sensing device arrangement within the pulmonary arterial network in accordance with the present inventions;

[0021] FIG. 4 is a side view of a third sensing device arrangement within the pulmonary arterial network in accordance with the present inventions;

[0022] FIG. 5 is a side view of a fourth sensing device arrangement within the pulmonary arterial network in accordance with the present inventions;

[0023] FIG. 6 is a side view of a fifth sensing device arrangement within the pulmonary arterial network in accordance with the present inventions;

[0024] FIG. 7 is a side view of a sixth sensing device arrangement within the pulmonary arterial network in accordance with the present inventions;

[0025] FIG. 8 is a side view of a seventh sensing device arrangement within the pulmonary arterial network in accordance with the present inventions;

[0026] FIG. 9 is a side view of an eighth sensing device arrangement within the pulmonary arterial network in accordance with the present inventions;

[0027] FIG. 10 is a side view of a ninth sensing device arrangement within the pulmonary arterial network in accordance with the present inventions;

[0028] FIG. 11 is a side view of a tenth sensing device arrangement within the pulmonary arterial network in accordance with the present inventions;

[0029] FIG. 12 is a side view of an eleventh sensing device arrangement within the pulmonary arterial network in accordance with the present inventions;

[0030] FIG. 13 is a side view of an alternative embodiment of a fixation element used in the eleventh sensing device arrangement of FIG. 12;

[0031] FIG. 14 is a side view of another alternative embodiment of fixation element used in the eleventh sensing device arrangement of FIG. 12;

[0032] FIG. 15 is a side view of a still another alternative embodiment of a fixation element used in the eleventh sensing device arrangement of FIG. 12;

[0033] FIG. 16 is a side view of yet another alternative embodiment of fixation element used in the eleventh sensing device arrangement of FIG. 12;

[0034] FIG. 17 is a side view of yet another alternative embodiment of fixation element used in the eleventh sensing device arrangement of FIG. 12;

[0035] FIGS. 18A-18D are side views illustrating one method of implanting a sensing device within the pulmonary arterial network in accordance with the present inventions; and

[0036] FIGS. 19A-19H are side views illustrating other methods of implanting a sensing device within the pulmonary arterial network in accordance with the present inventions.

#### DETAILED DESCRIPTION OF EMBODIMENTS

[0037] Referring to FIG. 2, an implantable sensing device 20 constructed in accordance with the present inventions will now be described. The sensing device 20 is shown implanted within an anatomical vessel network, and in particular, the pulmonary arterial network of a patient. As previously described, blood flows from the right ventricle RV of the heart H, out through the main pulmonary artery MPA, which branches into the right pulmonary artery RPA and a left pulmonary artery LPA. The blood from the right pulmonary artery RPA further flows into various pulmonary artery branches PBR of the right pulmonary artery RPA.

[0038] The sensing device 20 generally comprises a proximal fixation element 22, a distal fixation element 24, a connecting element 26 mechanically coupling the proximal fixation element 22 to the distal fixation element 24, and a sensing element 28 mechanically coupled to the proximal fixation element 22 via another connecting element 30 opposite the connecting element 26 (i.e., the proximal fixation element 22 is between the connecting elements 26, 30). As shown in FIG. 2, the proximal fixation element 22 is firmly engaged with the wall of the right pulmonary artery RPA at a longitudinal location proximal to a side branch SBR, while the distal fixation element 24 is firmly engaged with the wall of the side branch SBR.

[0039] It can be appreciated that the use of two fixation elements 22, 24 effectively increases the anchoring force between the sensing device 20 and the vessel wall of the pulmonary arterial network in the longitudinal direction, thereby minimizing the chance that the sensing device 20 will migrate within the right pulmonary artery RPA after implantation. In addition, because the distal fixation element 24 is disposed in the side branch SBR transverse to the lumen of the right pulmonary artery RPA, the anchoring force between the sensing device 20 and the vessel wall of the pulmonary arterial network is also increased in a rotational direction about the longitudinal axis of the right pulmonary artery RPA.

[0040] Advantageously, the connecting element 26 allows the fixation elements 22, 24 to articulate relative to each other, so that the distal fixation element 24 can be more easily disposed within the pulmonary branch BR, while the proximal fixation element 22 is disposed within the right pulmonary artery RPA. Also, the only portion of the sensing device 20 that is within the bifurcation between the right pulmonary artery RPA and the side branch SBR is the relatively low profile connecting element 26. As a result, very little force will be applied to the sensing device 20 by the blood flowing into the side branch SBR from the right pulmonary artery RPA, thereby increasing the stability of the sensing device 20 within the right pulmonary artery RPA, as well as decreasing the chance of embolism that may otherwise result from clots formed by the obstructed blood flow. In addition, because the connecting element 26 has a low profile, future access to the side branch SBR is not significantly hindered, thereby preserving the capability of catheterizing the side branch SBR if necessary or desired.

[0041] The other connecting element 30 may be rigid, so as to maintain the sensing element 28 at a constant position, or can be flexible, so as to enable movement of the sensing element 28 within the vessel lumen. In the illustrated embodiment, the other connecting element 30 maintains the sensing element 28 between the vessel wall and the center of the vessel lumen, e.g., between 0.05 mm and 0.8r, where r is the radius of the vessel lumen. For example, for a lumen having a radius of  $r=10$  mm, the sensing element 28 can be positioned at a distance between 0.05 mm and 8 mm from the vessel wall. In alternative embodiments, the sensing element 28 can be located either in contact with the vessel wall, at the vicinity of the vessel wall, or in any other convenient location within the vessel lumen. In these cases, the sensing element 28 may be connected directly to the proximal fixation element 22.

[0042] As illustrated in FIG. 2, each of the fixation elements 22, 24 has an expandable stent-like configuration

having one or more struts coupled together to provide an outwardly urging radial force against the vessel wall. In the illustrated embodiment, the resilient struts are in an open radial zigzag configuration. Alternatively, the resilient struts may be in a closed radial zigzag configuration, as illustrated in FIG. 3. In either case, the expanded sizes, and in particular the diameters, of the fixation elements **22**, **24** are individually selected to provide the necessary anchoring force within the respective vessel segments in which they are intended to be disposed; in this case, within the right pulmonary artery RPA and the side branch SBR, so that the expanded diameter of the proximal fixation element **22** will be greater than the expanded diameter of the distal fixation element **24**.

[0043] In the illustrated embodiment, the struts of the fixation elements **22**, **24** are composed of a suitable material that allows the fixation elements **22**, **24** to self-expand radially outward in the absence of a compressive force. To this end, the fixation elements **22**, **24** may be manufactured from a wire, a laser cut tube, or a chemical etched tube or metal sheet composed of a suitable biocompatible material, such as nickel-titanium alloy, stainless steel, titanium, or cobalt-based alloy, or to enhance the radio-opacity of the sensing device, tantalum, gold, platinum, or platinum-iridium. The fixation elements **22**, **24** may alternatively be composed of a polymer, including a shape memory polymer with or without the addition of radio-opaque material (e.g., barium sulfate). The cross-section of the struts may be, e.g., round, oval, rectangular, or any convenient shape. The thickness of the struts may be in the range of 0.05-0.5 mm. The struts may optionally include ridges, barbs, or hooks for preventing migration of the sensing device **20** within the vessel lumen.

[0044] Each of the connecting elements **26**, **30** may be composed of a suitable biocompatible material, such as nickel-titanium alloy, stainless steel, titanium, or cobalt-based alloy, or to enhance the radio-opacity of the sensing device, tantalum, gold, platinum, or platinum-iridium. The connecting elements **26**, **30** may alternatively be composed of a polymer, including a shape memory polymer with or without the addition of radio-opaque material (e.g., barium sulfate).

[0045] In the illustrated embodiment, the sensing element **28** is a pressure sensor for monitoring blood pressure within the blood vessel. However, any known sensor can be used, including, but not limited to, an accelerometer, a wall motion sensor, a flow sensor, temperature sensor, oxygen sensor, glucose sensor, coagulation sensor, an electrical activity sensor, and pH sensor. In alternative embodiments, another operative element can be located either in contact with the vessel wall, at the vicinity of the vessel wall, or in any other convenient location within the vessel lumen. The operative element may be another sensing element different from the sensing element **28**, or an energy source, such as a battery. For example, using an isolated electrical wire, the sensing element **28** can be electrically connected to a battery for enabling energy transfer from the battery to the sensing element **28**. Further details describing the structure and function of implantable sensing elements are disclosed in U.S. Pat. Nos. 6,764,446 and 7,024,248, which are expressly incorporated herein by reference.

[0046] Referring now to FIG. 4, the sensing device **20** is shown implanted within the vessel network in a different

configuration. In particular, the proximal fixation element **22** is firmly engaged with the wall of the right pulmonary artery RPA at a longitudinal location proximal to the side branch SBR, while the distal fixation element **24** is firmly engaged with the wall of the right pulmonary artery RPA at a longitudinal location distal to the side branch SBR.

[0047] As previously described with respect to FIG. 2, the use of two fixation elements **22**, **24** effectively increases the anchoring force between the sensing device **20** and the vessel wall of the pulmonary arterial network in the longitudinal direction, thereby minimizing the chance that the sensing device **20** will migrate within the right pulmonary artery RPA after implantation. In addition, because the fixation elements **22**, **24** articulate relative to each other, the non-uniformity of the diameter along the right pulmonary artery RPA does not significantly diminish the anchoring capability of the sensing device **20**. While the configuration shown in FIG. 4 does not use the side branch SBR as an anchoring mechanism, it does accommodate the side branch SBR by only locating the low-profile connecting element **26** at the bifurcation. The connecting element **26** may either cross the side branch SBR, or may even be offset from the side branch SBR to maintain the side branch SBR totally patent without crossing it.

[0048] Referring to FIG. 5, another implantable sensing device **40** constructed in accordance with the present inventions will now be described. The sensing device **40** is similar to the previously sensing device **40**, with the exception that the sensing element **28** is coupled between the fixation elements **22**, **24**. As can be seen, the sensing element **28** is suspended in the lumen of the right pulmonary artery RPA at the bifurcation. Preferably, the sensing element **28** is located as remotely as possible from the bifurcation to minimize blockage of the side branch SBR, which may otherwise increase the chances of migration and/or embolism. An optional connecting element **34** may be mechanically coupled between the fixation elements **22**, **24** to provide additional support, and thus, anchoring force to the sensing device **40**.

[0049] Referring to FIG. 6, another implantable sensing device **50** constructed in accordance with the present inventions will now be described. The sensing device **50** is similar to the previously described sensing device **20**, with the exception that the sensing element **28** is mounted to the connecting element **26** between the fixation elements **22**, **24**. As shown, the fixation element **22** is firmly engaged with the wall of the right pulmonary artery RPA at a longitudinal location distal to a side branch SBR, while the fixation element **24** is firmly engaged with the wall of the side branch SBR. As can be seen, the sensing element **28** is suspended in the lumen of the right pulmonary artery RPA at the bifurcation. Preferably, the sensing element **28** is located as remotely as possible from the bifurcation to minimize blockage of the side branch SBR, which may otherwise increase the chances of migration and/or embolism.

[0050] While the implantable sensing devices **20**, **40**, and **50** have been described as having only two fixation elements and only one sensing element, an implantable sensing device constructed in accordance with the present inventions can have more than two fixation elements and more than one sensing element. For example, referring to FIG. 7, an implantable sensing device **60** generally comprises a proxi-

mal fixation element **62**, a medial fixation element **64**, a distal fixation element **66**, a first connecting element **68** mechanically coupling the proximal fixation element **62** to the medial fixation element **64**, a second connecting element **70** mechanically coupling the distal fixation element **66** to the medial fixation element **64**, and three sensing elements **72**, **74**, **76** mechanically coupled to the respective fixation elements **62**, **64**, **66** via three connecting elements **78**, **80**, **82**. The fixation elements **62**, **64**, **66**, connecting elements **78**, **80**, **82**, and sensing elements **72**, **74**, **76** can be similarly constructed and function in the same manner as the same-named components described above.

[0051] As shown in FIG. 7, the proximal fixation element **62** is firmly engaged with the wall of the right pulmonary artery RPA at a longitudinal location proximal to the side branch SBR, the medial fixation element **64** is firmly engaged with the wall of the side branch SBR, and the distal fixation element **66** is firmly engaged with the wall of the right pulmonary artery RPA at a longitudinal location distal to the side branch SBR. Thus, it can be appreciated that the use of three fixation elements, one of which is disposed in the side branch SBR, further increases the anchoring force between the sensing device **60** and the vessel wall of the pulmonary arterial network in the longitudinal and rotational directions, thereby further minimizing the chance that the sensing device **20** will migrate within the right pulmonary artery RPA after implantation. In addition, the use of three sensing elements increases the volume and/or types of information sensed within the right pulmonary artery RPA.

[0052] While the fixation elements have thus far been described as having stent-like configurations, the fixation elements can have other configurations (which may be different between fixation elements of the same device) suitable for firmly engaging the walls of an anatomical vessel. For example, referring to FIG. 8, an implantable sensing device **90** is similar to the sensing device **20** illustrated in FIG. 2, with the exception that, instead of having a distal fixation element **24** in a stent-like configuration, it comprises two distal fixation elements **92**, **94** in coil-like configurations, which are mechanically coupled to the proximal fixation element **22** via respective connecting elements **96**, **98**. Each of the coiled fixation elements **92**, **94** comprises a single wire, which can have the same cross-section and be composed of the same material as the struts of the fixation elements **22**, **24** described above with respect to FIG. 2. As shown, the fixation element **92** is firmly engaged with the wall of the right pulmonary artery RPA at a location distal to the side branch SBR, and the fixation element **94** is firmly engaged with the wall of the side branch SBR, thereby providing the same anchoring advantages as the implantable sensing device **20** of FIG. 6.

[0053] Implantable sensing devices constructed in accordance with the present invention can have stabilization elements other than fixation elements. For example, referring to FIG. 9, an implantable sensing device **100** is similar to the sensing device **20** illustrated in FIG. 2, with the exception that, instead of a distal fixation element **24**, a stabilization element in the form of a flange **102** is mechanically coupled to the proximal fixation element **22**. In the illustrated embodiment, the flange **102** is formed by looping a strut of the fixation element **22** back onto itself. The flange **102** is pre-shaped (e.g., by an appropriate thermal treatment of a nickel-titanium alloy), such that it extends at an angle

from the fixation element **22** (i.e., transversely or obliquely to the longitudinal axis of the fixation element **22**) into contact with the wall of the side branch SBR, thereby increasing the anchoring force between the sensing device **20** and the pulmonary arterial network in both the longitudinal and rotational directions. Preferably, the flange **102** is composed of a material rigid enough to provide the necessary stability to the sensing device **100**.

[0054] Referring now to FIG. 10, another implantable sensing device **110** will be described. The sensing device **110** is similar to the previously described sensing device **100** of FIG. 9, with the exception that, instead of a proximal fixation element **22**, it includes the distal fixation element **24** configured to firmly engage the wall of the right pulmonary artery RPA at a location distal to the side branch SBR. As with the sensing device **100**, the sensing device **110** comprises a flange **112** mechanically coupled to the distal fixation element **24** and shaped, such that it extends at an angle from the fixation element **24** into contact with the wall of the side branch SBR, thereby increasing the anchoring force between the sensing device **100** and the pulmonary arterial network in both the longitudinal and rotational directions. The flange **112** may be formed by looping a strut of the fixation element **24** back onto itself, and is preferably composed of a material rigid enough to provide the necessary stability to the sensing device **110**.

[0055] Referring now to FIG. 11, still another implantable sensing device **120** will be described. The sensing device **120** is similar to the previously described sensing device **110** of FIG. 10, with the exception that it includes a flange **122** that is not pre-shaped to extend within the side branch SBR. Rather, the flange **122** is relatively straight, so that it remains within the lumen of the right pulmonary artery RPA. In addition, the sensing element **28** is mechanically coupled between the distal fixation element **24** and the flange **122**. Although the flange **122** is not designed to extend within the side branch SBR, and thus, does not significantly increase the anchoring force in a rotational direction about the longitudinal axis of the right pulmonary artery RPA, the flange **122** abuts the wall of the right pulmonary artery RPA, thereby preventing the sensing element **28** from hinging into the side branch SBR in response to the flow of blood from the right pulmonary artery RPA into the side branch SBR.

[0056] Referring to FIG. 12, yet another implantable sensing device **130** constructed in accordance with the present inventions will now be described. The sensing device **130** comprises a single fixation element **132** and the previously described sensing element **28** mechanically coupled to the fixation element **132**. The fixation element **132** is similar to either of the previously described fixation elements **22**, **24** in FIG. 2, with the exception that the length of the fixation element **132** is increased to allow it to cross the side branch SBR. For example, the length of the fixation element **132** may be equal to or greater than 35 mm. The increased length of the fixation element **132** increases the anchoring force between the sensing device **130** and the vessel wall of the pulmonary arterial network. To further increase the anchoring capability of the fixation element **132**, the proximal and distal edges of the fixation element **132** may be curved radially outward, as illustrated in FIG. 13, to provide a gripping force against the vessel wall that decreases longitudinal migration of the sensing device **130**. Alternatively, the proximal and distal edges of the fixation element **132**

may be curved radially inward, as illustrated in FIG. 14. In this manner, the resilient spring force of the fixation element 132 can be increased, thereby increasing its anchoring capability, without concern that the edges of the fixation element 132 will damage or otherwise irritate the wall of the right pulmonary artery RPA.

[0057] Notably, if the fixation element 132 is relatively uniform diameter along its length, its implantation into a conically shaped vessel may induce a spring forces that tends to push the sensing device 130 in the proximal direction. To address this, the fixation element 132 may be pre-shaped to have a conical geometry similar to the conical shape of the vessel (e.g., conical angle of 0-400 and length of 10-35 mm), as illustrated in FIG. 15. In this case, the fixation element 132 will be arranged in the vessel, such that the larger diameter of the fixation element 132 coincides with the large diameter of the vessel, and the small diameter of the fixation element 132 coincides with the small diameter of the vessel. Thus, the non-loaded fixation element 132 will have less of a tendency to move from its intended position. Alternatively, the fixation element 132 may be arranged as a mirror image of the vessel, as illustrated in FIG. 16. That is, the large diameter of the fixation element 132 coincides with the small diameter of the vessel, and the small diameter of the fixation element 132 coincides with the large diameter of the vessel. In this case, the shape and configuration of the fixation element 132 will straighten out the vessel, so that it is no longer conically shaped. Alternatively, as illustrated in FIG. 17, the distal edges of the fixation element 132 may be curved radially outward to provide a gripping force against the vessel wall that decreases longitudinal migration of the sensing device 130. Notably, these conical fixation element concepts can be applied to any of the previous embodiments.

[0058] The afore-described sensing devices can be delivered and implanted within the pulmonary arterial network of the patient using any suitable means, such as, e.g., a delivery catheter. For example, referring to FIGS. 18A-18D, a method of delivering the sensing device 20 within the pulmonary arterial network of a patient will now be described. The delivery system 150 includes a flexible catheter 152 configured for being delivered through the vasculature of a patient, and a pusher element 154 slidably disposed within the lumen of the catheter 152. The sensing device 20, and in particular, the sensing element 28, is detachably coupled to the distal end of the pusher element 154 using suitable means, such as a mechanical interference or electrolytic arrangement.

[0059] In the illustrated embodiment, the pusher element 154 is capable of being rotated relative to the catheter 152, so that the sensing device 20 can be implanted within the pulmonary arterial network in a specific circumferential location. That is, it may be desirable for the sensing element 28 to be located at the top of the vessel wall or at the bottom of the vessel wall. It may also be desirable to maintain the rotational orientation of the fixation elements 22, 24 relative to each other, so that the connecting element 26 runs along one side of the vessel wall instead of traversing the lumen of the vessel in the case where the one of the fixation elements 22, 24 is rotationally misaligned by 180 degrees.

[0060] To this end, a radio-opaque marker 156 is disposed on the sensing device 20 in a manner that allows the

orientation of the sensing device 20 to be determined via fluoroscopic imaging. The radio-opaque marker 156 may take the form of a material (e.g., platinum, gold, tantalum, or other commonly used radio-opaque material) coated on the sensing element 28 (as shown in the figures), or may take the form of a wire composed of the same material, which may, e.g., be crimped onto one or both of the fixation element 22, 24, or may even take the form of the connecting element 26 itself.

[0061] In the illustrated method, the sensing device 20 will be delivered into the pulmonary arterial network in the configuration illustrated in FIG. 2; i.e., with the distal fixation element 24 disposed within the side branch SBR and the proximal fixation element 22 disposed in the right pulmonary artery RPA at a longitudinal location proximal to the side branch SBR. As shown in FIG. 18A, the catheter 152 is advanced from the right ventricle RV of the heart, through the main pulmonary artery MPA, and into the lumen of the right pulmonary artery RPA. As can be seen, the sensing device 20 is loaded into the delivery catheter 152, such that the distal fixation element 24 will be deployed prior to the proximal fixation element.

[0062] As shown in FIG. 18B, the distal end of the catheter 152 is advanced into the side branch SBR (or alternatively, at the bifurcation within the right pulmonary artery RPA, but deflected towards the opening of the side branch SBR), and the pusher element 154 is distally advanced to push the distal fixation element 24 out from the catheter 152 and into the lumen of the side branch SBR. As previously discussed, the distal fixation element 24 is composed of a resilient material that causes it to self-expand in the absence of a compressive force. As a result, the distal fixation element 24 will automatically expand radially outward into firm contact with the wall of the side branch SBR once it is deployed from the catheter 152. Alternatively, if the distal fixation element 24 is not capable of self-expanding, a balloon can be used to radially expand the distal fixation element 24 into firm contact with the vessel wall.

[0063] As shown in FIG. 18C, the catheter 152 is then pulled in the proximal direction, so that the distal end of the catheter 152 is located within the right pulmonary artery RPA, and the pusher element 154 is distally advanced to push the proximal fixation element 22 out from the catheter 152 into the lumen of the right pulmonary artery RPA, where it automatically expands radially outward (or alternatively radially expands with the aid of a balloon) into firm contact with the wall of the right pulmonary artery RPA. As shown in FIG. 18D, the pusher element 154 is distally advanced further to push the sensing element 28 out from the catheter 152 into the lumen of the right pulmonary artery RPA, and the pusher element 154 is detached from the sensor element 28.

[0064] Similar delivery techniques can be used to form the configurations within the pulmonary arterial network illustrated in FIGS. 3-8. With respect to the configurations illustrated in FIGS. 9 and 10, the sensing devices can be implanted in the pulmonary arterial network by dragging the flange of the sensing device proximally or distally within the right pulmonary artery RPA until the flange locates itself into the side branch SBR, as illustrated in FIGS. 19A-19H.

[0065] For example, as shown in FIG. 19A, the sensing device 100 is loaded into the delivery catheter 152, such that

the flange **102** will be deployed prior to the fixation element **22**. As shown in FIG. **19B**, the distal end of the catheter **152** is advanced to a location in the right pulmonary artery RPA distal to the side branch SBR, and the pusher element **154** is distally advanced to push the flange **102** out from the catheter **152** and into contact with the wall of the right pulmonary artery RPA. As shown in FIG. **19C**, the catheter **152** is pulled in the proximal direction until the flange **102** catches within the side branch SBR.

[**0066**] As an alternative to the steps illustrated in FIGS. **19B** and **19C**, the distal end of the catheter **152** can be advanced to a location in the right pulmonary artery RPA proximal to the side branch SBR, and the pusher element **154** is distally advanced to push the flange **102** out from the catheter **152** and into contact with the wall of the right pulmonary artery RPA, as illustrated in FIG. **19D**, after which the catheter **152** is pushed in the distal direction until the flange **102** catches within the side branch SBR.

[**0067**] In any event, once the flange **102** is located within the side branch SBR, the pusher element **154** is distally advanced to push the fixation element **22** out from the catheter **152** into the lumen of the right pulmonary artery RPA, where it automatically expands radially outward into firm contact with the wall of the right pulmonary artery RPA, as shown in FIG. **19E**. The pusher element **154** is distally advanced further to push the sensing element **28** out from the catheter **152** into the lumen of the right pulmonary artery RPA, and the pusher element **154** is detached from the sensor element **28**, as illustrated in FIG. **19F**.

[**0068**] A similar method can be utilized to implant the sensing device **110** of FIG. **10**, with the exception that the fixation element **24** will need to be deployed out from the catheter **152** before the flange **112**, as illustrated in FIG. **19G**. In this case, before the sensing element **28** is detached from the pusher element **154**, the catheter **152** is pulled in the proximal direction, thereby displacing the entire sensing device **110**, including the expanded fixation element **24**, within the right pulmonary artery RPA until the flange **112** is located within the side branch SBR, as illustrated in FIG. **19H**. After the sensing device **110** is properly located, the pusher element **154** is detached from the sensor element **28**.

[**0069**] The sensing device **120** illustrated in FIG. **11** can be implanted within the pulmonary arterial network simply by deploying the fixation element **24** in the right pulmonary artery RPA at a location distal to the side branch SBR, pulling the catheter **152** in the proximal direction to deploy the sensor **28** and flange **122** within the right pulmonary artery RPA, and detaching the pusher element **154** from the sensor element **28**. The sensing device **130** illustrated in FIG. **12** can be implanted within the pulmonary arterial network simply by deploying the fixation element **24** in the right pulmonary artery RPA at a location at the side branch SBR, pulling the catheter **152** in the proximal direction to deploy the sensor **28** within the right pulmonary artery RPA, and detaching the pusher element **154** from the sensor element **28**.

[**0070**] As previously discussed, the distal fixation element **24** is composed of a resilient material that causes it to self-expand in the absence of a compressive force. As a result, the distal fixation element **24** will automatically expand radially outward into firm contact with the wall of the side branch SBR once it is deployed from the catheter

**152**. Alternatively, if the distal fixation element **24** is not capable of self-expanding, a balloon can be used to radially expand the distal fixation element **24** into firm contact with the vessel wall.

[**0071**] While the sensing devices have been illustrated and described as being implanted within the pulmonary artery PA, it should be appreciated that the sensing devices can be implanted in other blood vessels of the patient's body, e.g., the vena cava, pulmonary vein, coronary sinus, aorta, subclavian artery, iliac artery, and carotid artery. While the inventive method lends itself well to the implantation of the sensing devices in blood vessels, it should be appreciated that the sensing devices can be implanted in other anatomical vessels, such as the esophagus, intestine, trachea, bronchial tubes, etc. Lastly, while the present implantation techniques have been described with respect to sensing devices, the same implantation techniques can be utilized to implant therapeutic devices (e.g., a drug releasing device or neurostimulator for treating arrhythmia, pain, or neurological disturbances or for stimulating the gastrointestinal system or urinary system) within the anatomical vessels of patients.

[**0072**] Although particular embodiments of the present invention have been shown and described, it should be understood that the above discussion is not intended to limit the present invention to these embodiments. It will be obvious to those skilled in the art that various changes and modifications may be made without departing from the spirit and scope of the present invention. Thus, the present invention is intended to cover alternatives, modifications, and equivalents that may fall within the spirit and scope of the present invention as defined by the claims.

What is claimed:

1. An implant for sensing parameters within an anatomical vessel network of a patient, comprising:
  - a first fixation element having an expanded geometry for firmly engaging a wall of the vessel network at a first longitudinal location;
  - a second fixation element having an expanded geometry for firmly engaging the wall of vessel network at a second longitudinal location;
  - a connecting element mechanically coupling the first and second fixation elements together in an articulating manner; and
  - a sensing element mechanically coupled to the first fixation element opposite the connecting element.
2. The implant of claim 1, wherein the vessel network is a blood vessel network.
3. The implant of claim 2, wherein at least one of the first and second longitudinal locations is in a right pulmonary artery.
4. The implant of claim 1, wherein the vessel network has substantially differing diameters at the first and second longitudinal locations.
5. The implant of claim 1, wherein the first and second longitudinal locations are in a single anatomical vessel.
6. The implant of claim 1, wherein the first longitudinal location is in a main anatomical vessel, and the second longitudinal location is in an anatomical vessel branch of the main anatomical vessel.

7. The implant of claim 1, wherein each of the first and second fixation elements is selected from the group consisting of a stent and a coil.

8. The implant of claim 1, wherein the sensing element comprises one or more of a pressure sensor, an accelerometer, a wall motion sensor, a flow sensor, a temperature sensor, an oxygen sensor, a glucose sensor, a coagulation sensor, an electrical activity sensor, and a pH sensor.

9. The implant of claim 1, further comprising:

a third fixation element having an expanded geometry for firmly engaging the wall of vessel network at a third longitudinal location; and

another connecting element mechanically coupling the second and third fixation elements together in an articulating manner.

10. The implant of claim 1, further comprising a transmitter configured for wirelessly transmitting information sensed by the sensing element to a remote receiver.

11. A method of implanting a sensing device within an anatomical vessel network of a patient, the method comprising:

expanding a fixation element of the device into firm contact with a wall of a main anatomical vessel; and

locating a stabilization element of the device into contact with a wall of an anatomical vessel branch of the main anatomical vessel.

12. The method of claim 11, wherein the anatomical vessel network is a blood vessel network.

13. The method of claim 12, wherein the main anatomical vessel is a right pulmonary artery.

14. The method of claim 11, wherein the fixation element is selected from the group consisting of a stent and a coil.

15. The method of claim 11, wherein the stabilization element is a second fixation element that is expanded into firm contact with the wall of the anatomical vessel branch.

16. The method of claim 11, wherein the stabilization element resists rotation of the fixation element about a longitudinal axis of the main anatomical vessel.

17. The method of claim 11, further comprising expanding a third fixation element of the device into firm contact with the wall of the main anatomical vessel, wherein the first fixation element is located proximal to the anatomical vessel branch, and the third fixation element is located distal to the anatomical vessel branch.

18. The method of claim 11, further comprising locating a sensing element of the sensing device within the main

anatomical vessel when the first fixation element is firmly engaged with the wall of the main anatomical vessel and the stabilization element is in contact with the wall of the anatomical vessel branch.

19. The method of claim 11, further comprising operating the sensing element to measure one or more of a pressure, acceleration, wall motion, fluid flow, temperature, oxygen level, glucose level, coagulation, electrical activity, and pH level within the anatomical vessel.

20. The method of claim 11, further comprising wirelessly transmitting sensed information from the sensing device.

21. A method of implanting a sensing device within an anatomical vessel network having a main anatomical vessel and an anatomical vessel branch of the main anatomical vessel, the method comprising:

expanding a first fixation element of the device into firm contact with the wall of the main anatomical vessel at a longitudinal location proximal to the anatomical vessel branch; and

expanding a second fixation element of the device into firm contact with the wall of the main anatomical vessel at a longitudinal location distal to the anatomical vessel branch.

22. The method of claim 21, wherein the anatomical vessel network is a blood vessel network.

23. The method of claim 22, wherein the main anatomical vessel is a right pulmonary artery.

24. The method of claim 21, wherein each of the first and second fixation elements is selected from the group consisting of a stent and a coil.

25. The method of claim 21, further comprising expanding a third fixation element of the device into firm contact with the wall of the anatomical vessel branch.

26. The method of claim 21, wherein a sensing element of the device is located within the main anatomical vessel when the first and second fixation elements are firmly engaged with the wall of the main anatomical vessel.

27. The method of claim 21, further comprising measuring one or more of a pressure, acceleration, wall motion, fluid flow, temperature, oxygen level, glucose level, coagulation, electrical activity, and pH level within the anatomical vessel.

28. The method of claim 21, further comprising wirelessly transmitting sensed information from the sensing device.
