ABSTRACT

A surgical system includes a flexible steerable needle and a shape sensor for measuring the shape of the needle. The surgical system can be manual (e.g., laparoscopic), robotic, or any combination of the two. By directly measuring the shape of the needle, complex and potentially inaccurate modeling of the needle to determine trajectory and insertion depth can be avoided in favor of much more robust direct measurement and modeling of needle shape and/or pose.

STEERABLE FLEXIBLE NEEDLE WITH EMBEDDED SHAPE SENSING

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of U.S. Provisional Application No. 61/599,015 filed Feb. 15, 2012 and U.S. Provisional Application No. 61/594,959 filed Feb. 3, 2012, which are incorporated by reference herein in their entirety.

BACKGROUND

[0002] Aspects of this disclosure are related to shape sensing in a minimally invasive surgical instrument, and more particularly to the incorporation of shape sensing capabilities into a flexible needle.

[0003] Minimally invasive surgical procedures typically rely on some sort of instrument position monitoring to ensure proper access to, and behavior at, the target surgical location. Conventional minimally invasive surgical instruments are generally either formed from generally rigid, elongate elements (e.g., laparoscopic or robotic systems) or highly flexible systems designed to follow a predetermined anatomic path (e.g., angioplasty balloon catheters). In either case, position monitoring typically involves localized tracking.

[0004] For example, the overall shape of an instrument formed from rigid bodies can be determined via monitoring of just the extrema (e.g., the joints and ends) of those elements. For example, the shape of a rigid three-linkage robotic arm having two rotational joints (single degree of freedom for each joint) can be modeled using measurements from just the two rotational joints.

[0005] For catheter-based procedures, it is generally the catheter tip position that is critical, with the length of the catheter simply residing within a vessel in the body. For example, in an angioplasty procedure, the guidewire and/or balloon catheter tip must be positioned at the arterial blockage, and so the guidewire/balloon catheter tip is monitored (typically via direct visualization). The remaining guidewire/catheter length is not actively monitored, except in an incidental sense to the extent the remaining length is shown during fluoroscopic visualization of the tip advancement.

[0006] However, increasingly more complex minimally invasive surgical systems can require enhanced instrument position monitoring for safe and effective use. For example, the development of flexible, steerable needles provides an opportunity for procedures such as biopsy and/or therapeutic treatment, such as ablation treatments or radioactive seeds placement, at internal locations that would be problematic to access via a straight path—e.g., if it would be undesirable to puncture any intervening anatomy. Flexible, steerable needles can be delivered to the target site by direct penetration into the tissue, such as for example in the case of transcutaneous biopsy needles for the liver or other internal organs. Flexible, steerable needles can be delivered to the target site making use of the channel of an endoscope or a catheter, such as for example in the case of transluminal lung or stomach biopsy.

[0007] As used herein, steerable needles refer to a broad category of flexible needles with control inputs at the base (i.e., outside the body of the patient) and distal regions meant for piercing or puncturing target tissue. Depending on the shape and mechanical properties of the needle, interaction

forces between the needle and the patient anatomy (i.e., the target tissue and/or any intervening anatomy between the surgical entry point and the target tissue) can cause the needle to deflect, such that steering can be provided by simply applying rotation to the base of the needle. Alternatively or additionally, a steerable needle can include active actuators to provide shaping and directionality. Steerable needles generally have a high axial stiffness and a tip shape that allows them to puncture or penetrate tissue with minimal axial compression, as compared to catheter-type devices that have a low axial stiffness and are not suited to penetrate or puncture.

[0008] Note that the term “flexible” in association with a steerable needle should be broadly construed. In essence, it means the needle can be bent without harm. For example, a flexible steerable needle may include a series of closely spaced components that are similar to “vertebrae” in a snake-like arrangement. In such an arrangement, each component is a short link in a kinematic chain, and movable mechanical constraints (e.g., pin hinge, cup and ball, and the like) between each link may allow one (e.g., pitch) or two (e.g., pitch and yaw) degrees of freedom (DOF) of relative movement between the links. As another example, a flexible steerable needle may be continuous, such as a closed bendable tube (e.g., nitinol, polymer, and the like) or other bendable piece (e.g., kerf-cut tube, helical coil, and the like).

[0009] At the same time, the use of a flexible needle in a minimally invasive fashion can be significantly more complicated than conventional robotic or laparoscopic procedures. Not only is the variability in the actual shape of a steerable needle much greater than that of a linkage of rigid elements, but the needle flexibility can greatly increase susceptibility to deviation from a target trajectory due to variations in tissue characteristics (e.g., scar tissue, or otherwise denser than expected tissue, may result in greater than expected curvature of the flexible needle).

[0010] Accordingly, it is desirable to provide a steerable needle system that can be effectively used in minimally invasive surgical procedures.

SUMMARY

[0011] By incorporating a shape sensor into a flexible needle, the shape and/or surgical trajectory of such a needle can be effectively monitored and controlled to enable efficient and effective procedure performance.

[0012] As used herein, steerable needles refer to a broad category of flexible needles with control inputs at the base (i.e., outside the body of the patient) and distal regions meant for piercing or puncturing target tissue. The control inputs allow the needle to be guided along a desired surgical trajectory to a target location within the patient. In some embodiments, the needle may include a tip geometry that imparts a directional motion as the tip passes through tissue, such that the control inputs can simply be a handle(s) or other control to axially rotate the needle. In other embodiments, the needle may include wires, cables, or any other actuation mechanism to allow for more direct control over the shape and direction of travel of the needle. In such embodiments, the control inputs would be configured to provide the appropriate manipulation or actuation energy to the actuation mechanism(s) of the needle.

[0013] Depending on the shape and mechanical properties of the needle, interaction forces between the needle and the patient anatomy (i.e., the target tissue and/or any intervening anatomy between the surgical entry point and the target tis-

sue) can cause the needle to deflect and move along curved trajectories. The shape and/or direction of these trajectories can be influenced through the control inputs. Steerable needles can be used in minimally invasive clinical procedures for diagnosis and treatment of difficult to reach targets, e.g., in prostate biopsy and brachytherapy.

[0014] In some embodiments, a steerable needle can be a highly flexible (e.g., nitinol) needle with an asymmetric beveled tip and control inputs for insertion and shaft rotation. As it is inserted into tissue, the needle moves approximately along a circular path in the direction of the bevel. Rotating the needle shaft causes the bevel direction to change, thereby causing the needle shape and/or trajectory direction to change as the needle is moved through the patient anatomy. In other embodiments, a steerable needle can be a highly flexible (e.g., nitinol) needle with a pre-bent tip section and control inputs for insertion and shaft rotation. In this case, the needle moves along an approximately circular trajectory in the direction of the pre-bent tip (the lowest-energy state of the needle), wherein shape and/or trajectory direction changes can be effected via needle shaft rotation. In yet other embodiments, a steerable needle can be a highly flexible needle with an asymmetric tip (either beveled or pre-bent) that is controlled from the base by shaft insertion, shaft rotation, and bending at the entry point to control shape and/or trajectory direction. In various other embodiments, a steerable needle can be a concentric-tube device in which several flexible pre-bent tubes are assembled concentrically. The external control inputs determine the relative orientation and sliding amount of the different flexible tubes. The tip position and orientation can be changed by sliding and rotating the pre-bent tubes using the control inputs, thereby enabling control over shape and/or trajectory direction in use.

[0015] In some embodiments, a steerable needle can be fitted with a shape sensor(s) that measures the continuous shape of the needle. The sensor can be placed in a separate lumen in the wall of the needle, tacked in place (optionally in grooves) on the inside or outside of the needle wall, be removably inserted into the lumen of the needle (e.g., as part of a stylet), or otherwise coupled to the flexible needle along at least a portion of its length. The use of the interior lumen of the needle beneficially avoids the requirement of extra wall thickness or size.

[0016] The information obtained from the shape sensor can be used in various ways. For example, from the measured shape the total insertion depth into the tissue as well as the tip position and orientation can be determined. These variables can be used in a servo-loop to precisely control the needle insertion and orientation—instead of measuring just the proximal insertion and rotation amounts on the control inputs and assuming perfect transfer to the tip, the shape sensor can be used to directly measure the distal insertion and rotation, independent from the torsional and axial flexibility of the needle and the effects of friction and normal forces between the needle and the tissue.

[0017] In another embodiment, the measured tip position and orientation (as computed from the shape information) can be used in planning algorithms that compute feasible paths from the current needle position to the target location. The shape sensor can be used to measure the needle pose in place of or in addition to (potentially imprecise and noisy) imaging techniques.

[0018] In another embodiment, the shape sensor can be used to identify unknown model parameters in the biome-

chanical model of the tissue, as used in the planning software. For example, the bend radius of the trajectory of a steerable needle depends on the properties of the needle as well as the local properties of the surrounding tissue. These properties are hard to predict, but the shape sensor can be used to measure current actual bend radius of the trajectory to update model parameters.

[0019] In another embodiment, where one of the control inputs is bending the needle base near the entry point of the tissue, the shape sensor information, in conjunction with the needle material properties, can be used to estimate and locally update the kinematic mapping between needle base motions and needle tip motions. This mapping can be used to control the base of the needle for desired tip motion.

[0020] In another embodiment, the shape measurements can be used to detect undesired motions of the needle shaft, such as buckling and large deviations from the expected or allowed path. In conjunction with a mechanical model of the needle, the measured needle shape can also be used to estimate forces applied along the needle shaft. This could be used to identify points where high force is being applied to tissue.

[0021] In another embodiment, the shape sensor can be used in conjunction with imaging techniques to improve registration of the needle relative to preoperative data. The base, or some other portion of the shape sensor, can be registered to the image coordinate space by attaching an image-able fiducial to a portion of the fiber, or docking a fixed reference point on the fiber to a visible fiducial feature on the patient, or similar. The intraoperative imaging would provide a means to adapt needle trajectory in response to tissue motion or deformation. The measured shape of the needle could be used to assist in detecting and localizing the needle in intraoperative images, such that its position/orientation with respect to anatomical targets could be measured.

[0022] In another embodiment, the shape sensor can be used, in conjunction with a driving mechanism, to provide input in order to manually or automatically control an actuator that steers the flexible needle during a medical procedure.

BRIEF DESCRIPTION OF THE DRAWINGS

[0023] FIG. 1A is a block diagram of a minimally invasive surgical system that includes a steerable needle incorporating shape sensing.

[0024] FIG. 1B is a block diagram of a shape sensor processing system that can be part of the minimally invasive surgical system of FIG. 1A.

[0025] FIGS. 2A-2B are diagrams of steerable needle types usable with the minimally invasive surgical system of FIG. 1A.

[0026] FIGS. 3A-3F are various steerable needle/shape sensor combinations usable with the minimally invasive surgical system of FIG. 1A.

[0027] FIGS. 4-7 are operational flow diagrams for a minimally invasive surgical system incorporating a steerable needle with shape sensor.

DETAILED DESCRIPTION

[0028] By incorporating a shape sensor into a flexible needle, the shape and/or surgical trajectory of such a needle can be effectively monitored and controlled to enable efficient and effective procedure performance.

[0029] The embodiments below will describe various instruments and portions of instruments in terms of their state

in three-dimensional space. As used herein, the term “position” refers to the location of an object or a portion of an object in a three-dimensional space (e.g., three degrees of translational freedom along Cartesian X, Y, Z coordinates). As used herein, the term “orientation” refers to the rotational placement of an object or a portion of an object (three degrees of rotational freedom—e.g., roll, pitch, and yaw). As used herein, the term “pose” refers to the position of an object or a portion of an object in at least one degree of translational freedom and to the orientation of that object or portion of the object in at least one degree of rotational freedom (up to six total degrees of freedom). As used herein, the term “shape” refers to a set of poses, positions, or orientations measured along an object.

[0030] FIG. 1 shows an exemplary minimally invasive surgical system 100 that includes a steerable needle 110 that can be manipulated during a surgical procedure by an actuator 130. As used herein, steerable needles refer to a broad category of flexible needles with control inputs (i.e., actuator 130) at the base (i.e., outside the body of the patient) and distal regions meant for piercing or puncturing target tissue. Such needles can be used for diagnosis and/or treatment of difficult to access targets in a patient, such as in prostate biopsy, lung biopsy, liver biopsy, and brachytherapy, among others. Note that in various embodiments, system 100 can include any number of steerable needles, as indicated by optional steerable needle 110-2 (along with any actuation, control, sensing, and/or processing elements required for the additional needles 110).

[0031] Actuator 130 can manipulate needle 110, for example, by steering needle 110 along a desired surgical trajectory to a target location within the patient, changing the shape of needle 110, and/or changing the orientation of needle 110. As described in greater detail below, in some embodiments, the needle may include a tip geometry that imparts a directional motion as the tip passes through tissue, such that the control inputs can simply be a handle(s) or other control to axially rotate the needle. In other embodiments, the needle may include wires, cables, or any other actuation mechanism to allow for more direct control over the shape and direction of travel of the needle. In such embodiments, the control inputs would be configured to provide the appropriate manipulation or actuation signals/energy to the actuation mechanism(s) of the needle.

[0032] System 100 further includes a continuous shape sensor 120 that is substantially aligned with at least a portion of steerable needle 110. Regardless of the specific steering mechanism provided for needle 110, usability of system 100 in a minimally invasive surgical procedure is enhanced by the inclusion of shape sensor 120. As described in greater detail below, the data read by shape sensor 120 is acquired and converted into usable shape information by a processor 140. The shape information can then be used to guide further manipulation of needle 110. A shape sensor is an elongate sensor that provides shape measurement over the length of the sensor. In contrast to a discrete position sensor, a shape sensor enables shape measurement via a single sensor. Note that a shape sensor may include a single continuous sensing region or multiple sensing regions distributed over the length of the sensor, so long as the data from the shape sensor as a whole can be used to determine the measured shape. The integrated nature of a shape sensor can be particularly useful in delivering accurate shape measurement of needle 110. This in turn

can enable more precise control and/or enhanced error correction to ensure that needle 110 accurately traverses a desired surgical trajectory.

[0033] Note that although shape sensor 120 is depicted and described as a single shape sensor for explanatory purposes, in various embodiments shape sensor 120 can include multiple shape sensors, where each shape sensor measures the shape of a continuous portion of the overall length of needle 110. Also, in various other embodiments, needle 110 can include multiple parallel shape sensors, as indicated by optional additional shape sensor(s) 120-2. Such multiple shape sensors can be used, for example, to provide for greater shape modeling precision or to compensate for temperature or other sensor-affecting factors. Various other usages will be readily apparent.

[0034] Shape sensor 120 can be coupled to needle 110 in a variety of ways. For example, FIG. 3A shows shape sensor 120 housed in a lumen 112A in a wall 110W of needle 110. Wall 110W further defines an interior needle lumen 111 for surgical use (e.g., material delivery or biopsy). In various embodiments, an optional securing feature 121A (e.g., a slot, ridge, threads, shoulder, or any other feature) can be provided on needle 110 (e.g., at the distal end region or anywhere along lumen 112A) to assist in securing, aligning, and/or orienting sensor 120 with needle 110. In such embodiments, shape sensor 120 can itself include a corresponding mating feature(s).

[0035] FIG. 3B shows another embodiment of needle 110 in which shape sensor 120 is attached to the outer surface of wall 110W. In some embodiments, wall 110W can include an optional outer groove 112B that can help to capture and/or align sensor 120 with needle 110. In various other embodiments, an optional securing feature 121B (e.g., a slot, ridge, threads, shoulder, or any other feature) can be provided on needle 110 (e.g., at the distal end region or anywhere along groove 112B) to assist in securing, aligning, and/or orienting sensor 120 with needle 110. In such embodiments, shape sensor 120 can itself include a corresponding mating feature(s).

[0036] FIG. 3C shows another embodiment of needle 110 in which shape sensor 120 is attached to the inner surface of wall 110W. In some embodiments, wall 110W can include an optional inner groove 112C that can help to capture and/or align sensor 120 with needle 110. In various other embodiments, an optional securing feature 121C (e.g., a slot, ridge, threads, shoulder, or any other feature) can be provided on needle 110 (e.g., at the distal end region or anywhere along groove 112C) to assist in securing, aligning, and/or orienting sensor 120 with needle 110. In such embodiments, shape sensor 120 can itself include a corresponding mating feature(s).

[0037] Note that in various other embodiments, multiple shape sensors 120 can be incorporated into needle 110. For example, and shown in FIG. 1A, an optional second shape sensor 120-2 can be affixed to needle 110 to provide additional shape measurement data for enhanced accuracy, error correction, temperature compensation, etc. Note that while both sensors are depicted as being positioned within inner lumen 111 of needle 110 for exemplary purposes, in various other embodiments, both shape sensors 120 can be on the outer surface of needle 110, or within wall 110W, or in any combination of inner surface, outer surface, and in-wall

placements. Note further that any number of shape sensors **120** can be present, and in any relative arrangement along needle **110**.

[0038] FIG. 3D shows another embodiment of needle **110** in which shape sensor **120** is positioned within needle lumen **111**. This configuration allows shape measurements of needle **110** to be taken during insertion and navigation until the surgical target location is reached. Shape sensor **120** can then be removed, as shape and position information is no longer required, and the surgical procedure can be performed using the (now clear) needle lumen **111**. In various embodiments, shape sensor **120** can be replaced within needle lumen **111** prior to removal of needle **110** from the patient. In some embodiments, shape sensor **120** can be part of a flexible stylet or guidewire sized to fit within needle lumen **111**. The placement of shape sensor **120** within needle lumen **111** beneficially avoids impact to needle wall **110W** and can allow for the use of larger diameter and potentially more accurate shape sensors **120**.

[0039] Note further that the tip design for steerable needle **110** can take any form or shape as required for the particular procedural requirements of a surgical procedure. In some embodiments, needle **110** can include a bevel tip (e.g., Baker needle tip), as shown in FIGS. 3A-3D. In various other embodiments, alternative tip geometries can be used. For example, FIG. 3E shows needle **110** with a rounded tip (e.g., Tuohy needle tip), and FIG. 3F shows needle **110** with a solid tip (e.g., Spottle needle tip). Various other tip designs will be readily apparent.

[0040] As further shown in FIG. 3F, in some embodiments needle **110** can include optional additional sensors **315** to provide further usage information. For example, sensor **315** can be a position sensor (e.g., EM sensor, accelerometer, etc.) providing localized position data that can be used with the shape data from shape sensor **120** to model the in-situ pose and/or shape of needle **110**. Although depicted in the solid distal tip **311** of needle **110** in FIG. 3F for exemplary purposes, in various other embodiments, additional sensor(s) **315** can be located anywhere on needle **110**, regardless of specific needle configuration.

[0041] Likewise, various mechanisms can be used to steer needle **110**. For example, depending on the shape and mechanical properties of needle **110**, interaction forces between needle **110** and the patient anatomy (i.e., the target tissue and/or any intervening anatomy between the surgical entry point and the target tissue) can cause needle **110** to deflect as it is advanced through that patient anatomy. The mechanism may be actuated, manually or automatically, using information from the shape sensor as input.

[0042] For example, in various embodiments, needle **110** can be made from a highly flexible material (e.g., nitinol) and have an asymmetric bevel tip or pre-bent tip, such as shown in FIG. 1A. When inserted into tissue, the bevel tip will cause needle **110** to move in a curved trajectory in the direction of the bevel. Steerability is provided by rotating needle **110** axially to cause the bevel direction, and hence the needle trajectory, to change. In such cases, actuator **130** can be anything from a knob(s), handle(s), or other manual interface, to active drivers such as a servo motor, or combinations of manual and automated actuators.

[0043] In various other embodiments, needle **110** can be steered via more active mechanisms. For example, FIG. 2A shows an embodiment of needle **110** formed from multiple coaxial curved needle segments **210A**, **210B**, **210C**, and

210D. Note that while four needle segments **210** are depicted for exemplary purposes, in various other embodiments needle **110** can include any number of segments. In use, actuator **130** can control the relative rotation and extension of segments **210A-210D**, thereby determining the shape and orientation of needle **110**. FIG. 2B shows another embodiment of needle **110** in which one or more control cables **215** are provided to which tension and/or extension forces can be applied to cause desired bending of needle **110**. Cable(s) can be controlled via mechanical tensioners, motor actuators, or any other mechanism. For example, in some embodiments, cable(s) **215** can include material that responds to thermal changes, such as nitinol wire(s) configured to contract in response to electrical current-induced heating (such as described in "A Nitinol Wire Actuated Stewart Platform", by Dunlop et al. (Proc. 2002 Australasian Conference on Robotics and Automation, Nov. 27-29, 2002), herein incorporated by reference in its entirety). Various other steering mechanisms will be readily apparent.

[0044] Regardless of the specific steering mechanism used with flexible needle **110**, the usability of system **100** in a minimally invasive surgical procedure is enhanced by the inclusion of shape sensor **120** and the shape information provided therefrom. Furthermore, such benefit accrues regardless of the particular mode of control applied to needle **110**. Specifically, in various embodiments, system **100** can be a purely manual system (e.g., an endoscopic instrument), in which actuator **130** is directly controlled by an optional manual controller **150**, as shown in FIG. 1A. In some embodiments, optional manual controller **150** can be actuator **130** (e.g., a knob, handle, or grip for rotating needle **110**), and in other embodiments optional manual controller can be a handle(s), trigger(s), lever(s), grip(s), and/or any other user interface for providing control inputs to actuator **130**, either via direct mechanical attachment or linkage, via electrical/electronic control, or any combination of the above. In various other embodiments, system **100** can be a robotic system in which control over needle **110** is provided via a console or other remote interface of an optional robotic platform **160**. In yet other embodiments, system **100** can incorporate elements of both direct control and robotic control (e.g., robotic system with manual override) and therefore include both optional manual controller **150** and optional robotic platform **160**.

[0045] In robotically-assisted or telerobotic surgery, the surgeon typically operates a control device to control the motion of surgical instruments at the surgical site from a location that may be remote from the patient (e.g., across the operating room, in a different room or a completely different building from the patient) or immediately adjacent to the patient. Thus in some embodiments, robotic platform **160** can include one or more manually-operated input devices, such as joysticks, exoskeletal gloves or the like, which are coupled (directly or indirectly) to actuator **130** with servo motors or other drive mechanisms for steering needle **110** to the surgical site. During a procedure, robotic platform **160** can, in some embodiments, provide mechanical articulation and control of a variety of surgical instruments in addition to needle **110**, such as tissue graspers, electrosurgical cautery probes, retractors, staplers, vessel sealers, endoscopes, scalpels, ultrasonic shears, suction/irrigation instruments, and the like, that each perform various functions for the surgeon, e.g., grasping a blood vessel, or dissecting, cauterizing or coagulating tissue.

[0046] Shape sensor **120** can be any type of shape sensor capable of measuring the curvature of flexible needle **110** during surgical use. For example, in various embodiments,

shape sensor **120** can include a fiber optic shape sensor, such as described with respect to the systems and methods for monitoring the shape and relative position of an optical fiber in three dimensions described in U.S. patent application Ser. No. 11/180,389, filed on Jul. 13, 2005; U.S. provisional patent application Ser. No. 60/588,336, filed on Jul. 16, 2004, and U.S. Pat. No. 6,389,187, filed on Jun. 17, 1998, the disclosures of which are incorporated herein in their entireties. In some embodiments, an optical fiber in shape sensor **120** can comprise one or more cores (either single- and/or multi-mode) contained within a single cladding. Multi-core constructions can be configured to provide sufficient distance and cladding separating the cores such that the light in each core does not interact significantly with the light carried in other cores. In other embodiments, shape sensor **120** can include any number of optical fibers with the same or varying numbers of cores. In other embodiments, one or more of the cores in the optical fiber can be used for illumination and/or ablation.

[0047] In certain embodiments, shape sensor **120** can be a fiber optic bend sensor that includes a backscatter mechanism such as fiber Bragg gratings (FBGs), such as in product from Luna Innovations, Inc. (Blacksburg, Va.). In such embodiments, an array of FBGs can be provided within each core that comprises a series of modulations of the core's refractive index so as to generate a spatial periodicity in the refraction index. The spacing may be chosen so that the partial reflections from each index change add coherently for a narrow band of wavelengths, and therefore reflect only this narrow band of wavelengths while passing through a much broader band. During fabrication of the FBGs, the modulations are spaced by a known distance, thereby causing reflection of a known band of wavelengths. However, when a strain is induced on the fiber core, the spacing of the modulations will change, depending on the amount of strain in the core.

[0048] To measure strain, light is sent down the fiber, and the reflected wavelength is a function of the strain on the fiber and its temperature. This FBG technology is commercially available from a variety of sources, such as Smart Fibres Ltd. of Bracknell, England. When applied to a multicore fiber, bending of the optical fiber induces strain on the cores that can be measured by monitoring the wavelength shifts in each core. By having two or more cores disposed off-axis in the fiber, bending of the fiber induces different strains on each of the cores. These strains are a function of the local degree of bending of the fiber. Regions of the cores containing FBGs, if located at points where the fiber is bent, can thereby be used to determine the amount of bending at those points. These data, combined with the known spacings of the FBG regions, can be used to reconstruct the shape of the fiber.

[0049] Note, however, that while the use of FBGs are described above for exemplary purposes, any mechanism for creating backscatter could be used in shape sensor **120**, such as Rayleigh scattering, Raman scattering, Fluorescence scattering, and Brillouin scattering, among others. Typically, fiber optic shape sensors operate via optical time domain reflectometry (OTDR) or via optical frequency domain reflectometry (OFDR). The Kerr effect can also be used in shape sensor **120**.

[0050] Note further that in various other embodiments, any flexible, elongate sensor or combination of sensors can be used as shape sensor **120**. In various embodiments, shape sensor **120** can include a bend-enhanced fiber (BEF) sensor, such as ShapeTape from Measurand Inc. (Fredericton, New Brunswick, Canada), flexible piezoresistive sensor arrays or

wire strain detectors (such as described in "ULTRA-SENSITIVE SHAPE SENSOR TEST STRUCTURES BASED ON PIEZO-RESISTIVE DOPED NANOCRYSTALLINE SILICON", Alpuim et al. (NanoSpain 2008, Apr. 14-18, 2008), herein incorporated by reference in its entirety, and in "Electromechanical analysis of a piezoresistive pressure microsensor for low-pressure biomedical applications", Herrera-May et al. (REVISTA MEXICANA DE FÍSICA 55 (1) 14-24 Feb. 2009), herein incorporated by reference in its entirety), a nitinol wire for resistive strain measurement, an unaltered polarization-maintaining (PM) optical fiber, and/or any other shape sensing technologies.

[0051] Processor **140** detects the shape and position of steerable needle **110** and processes that information to assist in surgical procedures. Processor **140** is configured to interface with the specific type of sensor(s) in shape sensor **120** (e.g., providing interferometry and/or reflectometry capabilities for use with optical fiber sensors, or providing a voltage and/or current meter for use with resistance-based sensors). FIG. 1B shows an exemplary embodiment of processor **140** for processing the measurement data from a fiber optic shape sensor **120**. In view of this disclosure, instructions and modules used in any one of, or any combination of operations described with respect to processor **140** can be implemented in a wide variety of software and/or hardware architectures, such as software code modules running on dedicated processors, application specific integrated circuits (ASICs), field programmable gate arrays (FPGAs), or any other logic implementation, alone or in any combination.

[0052] Processor **140** in FIG. 1B includes an interrogator **141**, an input/output module **142**, a processor module **143**, and a shape data processing module **144**. Interrogator **141** interrogates the optical fiber of shape sensor **120** and provides shape information to input/output module **142**. Processor module **143** then processes the information from input/output module **142** using a shape data processing module **144** (e.g., stored in memory within processor **140**). The generated shape information for needle **110** can then be used to model the in-situ pose and/or shape of needle **110**. In some embodiments, known reference frame data (e.g., the position and orientation of actuator **130**/proximal end region of needle **110**) can be combined with the shape information for needle **110** to determine the in-situ pose and/or shape. In various other embodiments, positional measurements taken of needle **110** (e.g., via additional sensors on needle **110** or through visualization tracking) can be used with the shape data from shape sensor **120** to determine the in-situ pose and/or shape. More detailed description of an exemplary pose-determination process is provided in copending and commonly assigned U.S. patent application Ser. Nos. 12/164,829, and 12/618,082, both of which are incorporated herein by reference in their entireties.

[0053] Note that in various embodiments, processor **140** (or system **100**) can include optional additional processing modules to make use of the shape data provided by shape sensor **120**. In some embodiments, an optional path planning module **145** can be included to identify an appropriate trajectory (or multiple trajectory options) for either fully- or semi-automated control or for providing guidance for manual control over system **100**. In various other embodiments, if automated or semi-automated control is provided by system **100**, an optional control planning module **146** can be included to generate the appropriate control signals for actuator **130**, for example based on the output of path planning module **145**.

[0054] In various other embodiments, an optional error detection module **147** can be included to compare measured shape, pose, and/or position data against expected values (e.g., desired values or values predicted from a mathematical model). For example, in some embodiments, the measured data can be compared against model data to validate and/or update the model data. In other embodiments, the measured data can be compared to target data (e.g., comparing actual trajectory of needle **110** to a desired trajectory) to avoid excessive deviation from a desired behavior. In some embodiments, such error detection can provide notification to the surgeon via visual, aural, or tactile cues or reports. In various other embodiments, deviations can be presented graphically (e.g., on a video monitor, overlaying actual trajectory onto desired trajectory). In such embodiments, an optional graphics module **148** can also be included in processor **140** to provide the necessary graphical representation of the measurements of shape sensor **120**. In other embodiments, graphics module **148** can be included simply to provide a visual representation of the shape data measured by shape sensor **120**.

[0055] As noted above, a surgical procedure can be beneficially enhanced by measuring the shape of a steerable needle and then controlling the needle (e.g., adjusting the shape of the needle, changing the orientation of the needle (e.g., axial rotation), advancing/retracting the needle, etc.) based on that measured shape. Note that while the descriptions herein refer to the use of a steerable flexible needle with shape sensor in surgical applications for exemplary purposes, in various embodiments, the same methods and procedures can be used in animals (e.g., veterinary use), cadavers, artificial anatomic replicas, and/or computer simulations of surgical procedures.

[0056] FIG. 4 shows an exemplary flow diagram for the use of shape sensing in such a procedure. In a Shape Measurement step **410**, the shape of a steerable flexible needle (such as needle **110** described above) is measured. The measurement can be performed using any type of shape sensor capable of providing real time shape information for the flexible needle (such as shape sensor **120** described above). Then, in a Shape Modeling step **420**, the measured data is used to model the actual shape of the flexible needle.

[0057] Note that depending on the requirements of the surgical system and procedure itself, the specific level of shape modeling in step **420** can vary. For example, in some embodiments, step **420** may simply involve determining the standalone shape of the needle—for example to determine if the needle has reached a desired deployed state. In some other embodiments, step **420** can involve determining the shape of the needle along with its orientation (e.g., using additional reference frame information from the proximal (attachment) region of the needle to the actuator (such as actuator **130**, above), or from additional sensor data (such as sensor **315** above)). For example, FIG. 5 shows an embodiment of the flow diagram of FIG. 4 that includes an optional Pose Modeling step **522**.

[0058] The continuous shape modeling of step **420** can provide a significant procedural advantage over approaches limited to the use of catheters having a single position sensor (or several discrete sensors at particular locations), which can only estimate shape and orientation by assuming perfect mechanical transfer between the inputs and the measured locations. The actual shape measurements of step **420** can allow total insertion depth of the needle to be accurately determined, along with distal tip position and orientation.

This determination can be made regardless of the torsional and axial flexibility of the needle and any effects of friction and normal forces between the needle and the patient tissue, which would otherwise need to be precisely modeled to produce similar results using a discrete sensor system—an unwieldy and likely unmanageable approach for most surgical applications.

[0059] In some embodiments, step **420** can include the identification or refinement of model parameters in a biomechanical model of the tissue and/or kinematic model of the needle system, as indicated by optional Adjust Model Parameters step **523** in FIG. 5. For example, the actual behavior of the needle (e.g., bend radius) as it traverses a patient tissue or anatomical structure can be used to derive tissue density, changes in material (e.g., diseased or degenerative tissue regions exhibiting unexpected material properties, such as tumors, cysts, osteoporosis, etc.), or other difficult to predict and model anatomical aspects. In other embodiments, the actual needle trajectory can be used to estimate and update kinematic mapping between the actuator inputs and the actual needle movement (e.g., the tip and/or the shaft of the needle), thereby improving the responsiveness and accuracy of the needle control. In other embodiments, the actual needle trajectory can be used to calculate loading of the needle, at discrete locations or along its entire length, since the curvature(s) of the needle will be dependent at least in part on the local forces applied to the needle.

[0060] In some other embodiments, the pose information determinable in step **420** can be beneficially used to indicate or visualize the actual placement of the needle within a patient or the actual surgical trajectory being followed by the needle, as in an optional Path Modeling step **430**. For example, step **430** can include using the needle shape information determined in step **420** to determine one or more target trajectories for the continuing advance of the needle (e.g., based on needle properties, anatomical model properties, needle behavior up to current location, supplemental anatomical information (e.g., visualization, enhanced material properties based on actuation force required by needle, etc.), and/or any other path-affecting information), as indicated by an optional Path Planning step **531** in FIG. 5.

[0061] In various other embodiments, steps **420** and/or **430** can include comparing the actual needle shape and/or trajectory with an expected or desired shape/trajectory. Any deviation from the desired shape/trajectory can be identified and/or used to provide feedback to the surgeon as to potential corrective actions, depending on the magnitude of the deviation. For example, FIG. 6 shows a flow diagram in which step **420** includes an optional Detect Shape Deviation step **621** in which the measured shape is compared to an expected shape. The deviation can then be assessed in an Exceeds Threshold? step **622**, where if the deviation is greater than some preset limit, a notification is provided in an Error State step **623**. This notification can take any form, including a visual warning, an audible warning, an error message, a tactile indication, warning icon, and/or system freeze/recovery action, among others. In some embodiments, step **623** can result in procedure abort or restart, due to excessive needle deformation. In various other embodiments, if the shape deviation is less than a maximum deviation, a determination is made in an optional Correction Required? step **624**, wherein if the deviation is small enough, no adjustment to the needle shape is made, and the process simply continues. However, if the deviation is determined to require correction, such correction can be calculated

in a Determine Adjustment step 625. This adjustment can be provided to the surgeon as instructions, graphical representation, or any other means for conveying the information to the surgeon, or can be provided automatically to the system to cause automatic correction of the needle shape (e.g., providing appropriate control signals to the needle actuator).

[0062] In another example, FIG. 7 shows a flow diagram in which step 430 includes an optional Detect Path Deviation step 731 in which the measured needle trajectory is compared to an expected trajectory (e.g., a pre-operatively determined trajectory or an intraoperatively modeled trajectory). The deviation can then be assessed in an Exceeds Threshold? step 732, where if the deviation is greater than some preset limit, a notification is provided in an Error State step 733. This notification can take any form, including a visual warning, an audible warning, an error message, a tactile indication, warning icon, and/or system freeze/recovery action, among others. In some embodiments, step 733 can result in procedure abort or restart, due to excessive trajectory deviation. In various other embodiments, if the trajectory deviation is less than a maximum deviation, a determination is made in an optional Correction Required? step 624, wherein if the deviation is small enough, no adjustment to the needle shape and/or actuation control inputs is made, and the process simply continues. However, if the deviation is determined to require correction, such correction can be calculated in a Determine Adjustment step 625. This adjustment can be provided to the surgeon as instructions, graphical representation, or any other means for conveying the information to the surgeon, or can be provided automatically to the system to cause automatic correction of the needle trajectory (e.g., providing appropriate control signals to the needle actuator).

[0063] In some other embodiments, the shape and/or position of the needle can also be adjusted in an optional Needle Control step 440. For example, the shape and/or path information derived from step 420 and optional step 430, respectively, can be used to determine the appropriate advancement/retraction and/or shape adjustment for the needle. For instance, if steps 420 and/or 430 indicate that the needle shape is sub-optimal for completion of the desired procedure, the needle can be adjusted towards a more optimized shape in step 440 (e.g., by actively changing the needle shape, by changing the needle orientation to cause the desired shape change during advancement/retraction, and/or by performing any other shape-affecting action). Similarly, if steps 420 and/or 430 indicate that the trajectory of the needle is sub-optimal for completion of the desired procedure, the needle can be adjusted towards a more optimized path in step 440 (e.g., by changing needle shape, by changing the needle orientation (e.g., rotation), retracting the needle, and/or any other trajectory-impacting action). In various embodiments, this shape and/or trajectory adjustment can be performed manually, in response to surgeon cues (e.g., visual indication of deviation, sounds, or tactile indications when a deviation from the desired path is detected), automatically, or any combination of the above. In some embodiments, the specific controls applied to the needle actuator can be determined based on the shape sensor data, as indicated by an optional Control Planning step 532 in FIG. 5.

[0064] All examples and illustrative references are non-limiting and should not be used to limit the claims to specific implementations and embodiments described herein and their equivalents. The headings are solely for formatting and should not be used to limit the subject matter in any way,

because text under one heading may cross reference or apply to text under one or more headings. Finally, in view of this disclosure, particular features described in relation to one aspect or embodiment may be applied to other disclosed aspects or embodiments of the disclosure, even though not specifically shown in the drawings or described in the text.

1. A flexible needle comprising:
 - a shape sensor and
 - a connector adapted for connecting the shape sensor to a processor for determining the shape of the flexible needle based on data from the shape sensor.
2. The flexible needle of claim 1 wherein the shape sensor comprises at least one of an optical fiber, a fiber Bragg grating, a nitinol wire, and a piezoresistive element.
3. The flexible needle of claim 1 further comprising a wall defining an interior lumen, wherein the shape sensor is removably insertable into the interior lumen.
4. The flexible needle of claim 1 further comprising a wall defining an interior lumen, wherein the shape sensor is attached to the wall.
5. The flexible needle of claim 4, wherein the shape sensor is attached to an external surface of the wall.
6. The flexible needle of claim 4, wherein the shape sensor is attached to an internal surface of the wall.
7. The flexible needle of claim 4, wherein the wall comprises a groove, and wherein the shape sensor is at least partially positioned within the groove.
8. The flexible needle of claim 7, wherein the groove comprises one or more positioning features mated with the shape sensor and wherein the one or more positioning features prevents movement of the shape sensor along the groove.
9. The flexible needle of claim 8, wherein the one or more positioning features comprises at least one of a slot, a ridge, and a threaded section.
10. The flexible needle of claim 1 further comprising a wall having an interior surface and an exterior surface, the interior surface defining an interior lumen,
 - wherein a second lumen is defined between the interior surface and the exterior surface, and
 - wherein the shape sensor is positioned at least partially within the second lumen.
11. The flexible needle of claim 1 further comprising a plurality of concentric curved segments, wherein each of the plurality of concentric curved elements is independently rotatable and extendible.
12. The flexible needle of claim 1 further comprising at least one control cable, wherein flexion of the flexible needle is controlled by the control cable.
13. The flexible needle of claim 1 further comprising a distal tip portion wherein the distal tip portion comprises one of a bevel tip, a curved tip, and a solid tip.
14. The flexible needle of claim 1, further comprising a second shape sensor, at least a portion of the second shape sensor being substantially parallel to at least a portion of the shape sensor, wherein the connector is further adapted for connecting the second shape sensor to the processor for determining the shape of the flexible needle based on data from the shape sensor and the second shape sensor.
15. The flexible needle of claim 1, further comprising a position sensor, wherein the connector is further adapted for connecting the position sensor to the processor for determining a position of a section of the flexible needle based on data from the position sensor.

16. A surgical system comprising:
 a flexible needle including a shape sensor and a connector adapted for connecting the shape sensor to a processor;
 and
 an actuator for manipulating the flexible needle.
17. The surgical system of claim 16 further including the processor for determining a shape of the flexible needle based on data from the shape sensor.
18. The surgical system of claim 16, wherein the shape sensor comprises at least one of an optical fiber, a fiber Bragg grating, a nitinol wire, and a piezoresistive element.
19. The surgical system of claim 16, wherein the flexible needle comprises a wall defining an interior lumen and wherein the shape sensor is removably insertable into the interior lumen.
20. The surgical system of claim 19, wherein the shape sensor comprises a stylet sized to fit within the interior lumen.
21. The surgical system of claim 16, wherein the flexible needle comprises a wall defining an interior lumen, and wherein the shape sensor is attached to the wall.
22. The surgical system of claim 21, wherein the shape sensor is attached to an external surface of the wall.
23. The surgical system of claim 21, wherein the shape sensor is attached to an internal surface of the wall.
24. The surgical system of claim 21, wherein the wall comprises a groove, and
 wherein the shape sensor is at least partially positioned within the groove.
25. The surgical system of claim 24, wherein the groove comprises one or more positioning features mated with the shape sensor,
 wherein the one or more positioning features prevents movement of the shape sensor along the groove.
26. The surgical system of claim 25, wherein the one or more positioning features comprises at least one of a slot, a ridge, and a threaded section.
27. The surgical system of claim 16, wherein the flexible needle comprises a wall having an interior surface and an exterior surface, the interior surface defining an interior lumen,
 wherein a second lumen is defined between the interior surface and the exterior surface, and
 wherein the shape sensor is positioned at least partially within the second lumen.
28. The surgical system of claim 16, wherein the flexible needle comprises a plurality of concentric curved segments, wherein each of the plurality of concentric curved elements is independently rotatable and extendible.
29. The surgical system of claim 16, wherein the flexible needle comprises at least one control cable, and
 wherein flexion of the flexible needle is controlled by the control cable.
30. The surgical system of claim 16, wherein a distal tip of the flexible needle comprises one of a bevel tip, a curved tip, and a solid tip.
31. The surgical system of claim 16, wherein the flexible needle comprises a solid needle.
32. The surgical system of claim 16, further comprising a second shape sensor attached to the flexible needle, at least a portion of the second shape sensor being substantially parallel to at least a portion of the shape sensor, wherein the connector is further adapted for connecting the second shape

sensor to the processor for determining the shape of the flexible needle based on data from the shape sensor and the second shape sensor.

33. The surgical system of claim 16 wherein each of the shape sensor and the second shape sensor are attached to different concentric curved segments of the flexible needle.

34. The surgical system of claim 16, further comprising a position sensor attached to a section of the flexible needle, the processor determining a position of the section based on data from the position sensor.

35. The surgical system of claim 34, wherein the position sensor is attached to a distal tip of the flexible needle.

36. The surgical system of claim 35, further comprising a manual controller allowing direct user control over the actuator.

37. The surgical system of claim 16, further comprising a robotic surgical platform coupled to the actuator.

38. The surgical system of claim 16 wherein the flexible needle is a transcutaneous biopsy needle.

39. The surgical system of claim 16, wherein the flexible needle is an endoscopic biopsy needle.

40. The surgical system of claim 16, wherein the flexible needle is adapted to deliver a tissue ablation device.

41. The surgical system of claim 16, wherein the flexible needle is adapted to deliver radioactive seeds.

42. A method for performing surgery comprising:
 measuring a current shape of a flexible needle;
 creating a model of the current shape of the flexible needle;
 and

creating a model of a current in-situ pose of a section of the flexible needle using the model of the current shape of the flexible needle.

43. The method of claim 42 wherein the section of the flexible needle is a distal tip section of the flexible needle.

44. The method of claim 42, wherein measuring the current shape of the flexible needle comprises processing data from a shape sensor attached to a first section of the flexible needle to determine at least one bend radius for the first section of the flexible needle.

45. The method of claim 44, wherein creating the model of the current shape of the flexible needle comprises adjusting an initial shape model of the flexible needle based on the at least one bend radius.

46. The method of claim 42, further comprising determining a target travel path for the flexible needle based on the model of the current in-situ pose.

47. The method of claim 46, further comprising:
 moving the flexible needle; and
 comparing an actual travel path of the flexible needle with the target travel path.

48. The method of claim 47, wherein comparing the actual travel path of the flexible needle with the target travel path comprises providing user feedback when a threshold deviation between the actual travel path and the target travel path is detected.

49. The method of claim 42, further comprising
 determining a deviation between the model of the current shape of the flexible needle and an expected shape of the flexible needle; and
 generating an error state when the deviation exceeds a first predetermined threshold level.

50. The method of claim 49, further comprising determining an adjustment to the current shape of the flexible needle to reduce the deviation when the deviation exceeds a second

predetermined threshold level and does not exceed the first predetermined threshold level.

51. The method of claim 50, further comprising automatically applying the adjustment to the flexible needle.

52. The method of claim 50 further comprising providing feedback to a user for use in manually adjusting the flexible needle.

53. The method of claim 42, wherein creating the model of the current in-situ pose of the flexible needle comprises:

determining an expected shape of the flexible needle, the expected shape of the flexible needle being based on one or more modeling parameters for anatomy traversed by the flexible needle;

determining a deviation between the expected shape of the flexible needle and the model of the current shape of the flexible needle; and

updating at least one of the one or more modeling parameters based on the deviation.

54. The method of claim 42, wherein measuring the current shape of the flexible needle comprises reading data from a shape sensor aligned with the flexible needle.

55. The method of claim 54, wherein the shape sensor comprises a fiber Bragg grating.

56. The method of claim 54, wherein the flexible needle comprises a wall, and

wherein the shape sensor is attached to an external surface of the wall.

57. The method of claim 54, wherein the flexible needle comprises a wall defining an interior needle lumen, and

wherein the shape sensor is positioned at least partially within a second lumen within the wall.

58. The method of claim 54, wherein the flexible needle comprises a wall defining an interior needle,

wherein measuring reading the data from the shape sensor comprises gathering the data while the shape sensor is at least partially positioned within the interior needle lumen, and

wherein the method further comprises removing the shape sensor from the interior needle lumen.

59. The method of claim 42, further comprising:

measuring a current position of at least one portion of the flexible needle, and creating a model of the current position of the at least one portion of the flexible needle.

60. A method for guiding a flexible needle during a medical procedure, the method comprising:

measuring a shape of a flexible needle using a shape sensor; modeling the shape of the flexible needle; and driving an actuator for adjusting the shape of the flexible needle.

61. The method of claim 60, wherein measuring the shape of the flexible needle comprises reading shape data from the shape sensor at least partially aligned with the flexible needle.

62. The method of claim 60, wherein the shape sensor comprises at least one of an optical fiber, a piezoresistive sensor array, and a fiber Bragg grating.

63. The method of claim 60, wherein modeling the shape of the flexible needle comprises determining a pose of a section of the flexible needle.

64. The method of claim 63, wherein determining the pose of the flexible needle comprises reading position data from at least one position sensor on the flexible needle.

65. The method of claim 63, wherein determining the pose of the flexible needle comprises combining the shape of the flexible needle with reference frame data from the actuator.

66. The method of claim 60, further comprising determining a total insertion depth of the flexible needle based on the shape of the flexible needle.

67. The method of claim 60, wherein measuring the shape of the flexible needle comprises measuring the shape of the flexible needle in a target anatomy, and wherein the method further comprises updating a model of the target anatomy based on the shape of the flexible needle.

68. The method of claim 60, wherein driving the actuator comprises changing the shape of the flexible needle to achieve a desired trajectory for the flexible needle.

69. The method of claim 60, wherein modeling the shape of the flexible needle comprises generating an error condition when the shape of the flexible needle deviates from an expected needle shape by more than a threshold deviation.

70. The method of claim 60, wherein modeling the shape of the flexible needle comprises generating one or more possible trajectories for the flexible needle.

71. The method of claim 70, wherein driving the actuator comprises automatically changing the shape of the flexible needle to enable progress of the flexible needle along at least one of the one or more possible trajectories for the flexible needle.

72. The method of claim 70, wherein driving the actuator comprises:

applying articulation inputs to the flexible needle in response to control inputs from a user; and

providing feedback to the user when the articulation inputs result in a deviation from the one or more possible trajectories for the flexible needle.

73. The method of claim 70, wherein the feedback comprises at least one of auditory feedback, tactile feedback, and visual feedback.

74. The method of claim 60, wherein driving the actuator comprises providing a control input to the actuator, and wherein the method further comprising:

measuring a new shape of the flexible needle using the shape sensor;

modeling the new shape of the flexible needle; and

identifying a kinematic mapping between the control input and a motion of the flexible needle based on a change from the shape to the new shape.

75. The method of claim 60, further comprising calculating one or more forces applied to the flexible needle based on the shape of the flexible needle.

76. The method of claim 60, further comprising comparing a graphical representation of the shape of the flexible needle with a graphical representation of an expected shape of the flexible needle.
