Method and apparatus for the simultaneous use of ultrasound on a probe for imaging and therapeutic purposes. The probe limits the effects of undesirable interference noise in a display by synchronizing high intensity focused ultrasound (HIFU) waves with an imaging transducer to cause the noise to be displayed in an area of the image that does not overlap the treatment site. In one embodiment, the HIFU is first energized at a low power level that does not cause tissue damage, so that the focal point of the HIFU can be identified by a change in the echogenicity of the tissue caused by the HIFU. Once the focal point is properly targeted on a desired treatment site, the power level is increased to a therapeutic level. The location of each treatment site is stored and displayed to the user to enable a plurality of spaced-apart treatment sites to be achieved. As the treatment progresses, any changes in the treatment site can be seen in the real time, noise-free image. A preferred application of the HIFU waves is to cause lesions in blood vessels, so that the supply of nutrients and oxygen to a region, such as a tumor, is interrupted. The tumor will thus eventually be destroyed. In a preferred embodiment, the HIFU is used to treat disorders of the female reproductive system, such as uterine fibroids. The HIFU treatment can be repeated at spaced-apart intervals, until any remaining fibroid tissue is destroyed.

NOISE-FREE REAL TIME ULTRASONIC IMAGING OF A TREATMENT SITE UNDERGOING HIGH INTENSITY FOCUSED ULTRASOUND THERAPY

RELATED APPLICATIONS

[0001] This application is based on U.S. provisional patent application Serial No. 60/100,812; filed on Sep. 18, 1998, the benefit of the filing date of which is hereby claimed under 35 U.S.C. §119(e).

GOVERNMENT RIGHTS

[0002] This invention was made under contract with the United States Department of Defense, under Contract Number N00014-96-0630, and the United States government may have certain rights in the invention.

FIELD OF THE INVENTION

[0003] The present invention relates to ultrasonic imaging and therapy apparatus and method incorporating both ultrasonic observation and therapeutic waves, and more specifically to apparatus and method designed to allow real time, noise-free imaging of a treatment site to which high intensity focused ultrasound is directed.

BACKGROUND OF THE INVENTION

[0004] Ultrasound has gained acceptance as an imaging technique particularly well suited to providing information about a patient's internal structures without risk of exposure to potentially harmful radiation, as may occur when using X-ray imaging techniques. The first recorded use of ultrasound as an imaging technique was by Dr. Karl Dussik, a Psychiatrist at the hospital in Bad Ischl, Austria; who tried to locate brain tumors using ultrasound. He used two opposed probes, including one that transmitted ultrasound waves, while the other probe received them. With these probes, he transmitted an ultrasound beam through a patient's skull, and used the received signal to visualize the cerebral structure by measuring the ultrasound beam attenuation. He published his technique in 1942, in an article entitled, "Hyperphonography of the Brain."

[0005] Specially manufactured medical diagnostic equipment using ultrasound became available in the 1950's. An ultrasound examination is a safe diagnostic procedure that uses very high-frequency sound waves to produce an image of the internal structures of the body. Many studies have shown that these sound waves are harmless and may be used with complete safety, even on pregnant women, where the use of X-rays would be inappropriate. Furthermore, ultrasound examinations are sometimes quicker and typically less expensive than other imaging techniques.

[0006] More recently, the use of high intensity focused ultrasound (HIFU) for therapeutic purposes, as opposed to imaging, has received significant attention in the medical community. HIFU therapy employs ultrasound transducers that are capable of delivering 1,000-10,000 W/cm² at a focal spot, in contrast to diagnostic ultrasound where intensity levels are usually below 0.1 W/cm². A portion of the mechanical energy from these high intensity sound waves is transferred to the targeted location as thermal energy. The amount of thermal energy thus transferred can be sufficiently intense to cauterize tissue, or to cause tissue necrosis (by

inducing a temperature rise to beyond 70° C.) without actual physical charring of the tissue. Tissue necrosis can also be achieved by mechanical action alone (i.e., by cavitation that results in mechanical disruption of the tissue structure). Further, where the vascular system supplying blood to an internal structure is targeted, HIFU can be used to induce hemostasis. The focal point of this energy transfer can be tightly controlled so as to obtain tissue necrosis in a small target area without damaging adjoining tissue. Thus, deep-seated tumors can be destroyed with HIFU without surgical exposure of the tumor site.

[0007] A particular advantage of HIFU therapy over certain traditional therapies is that HIFU is less invasive. The current direction of medical therapy is progressively toward utilizing less-invasive and non-operative approaches, as will be evident from the increasing use of laparoscopic and endoscopic techniques. Advantages include reduced blood loss, reduced risk of infection, shorter hospital stays, and lower health care costs. HIFU has the potential to provide an additional treatment methodology consistent with this trend by offering a method of non-invasive surgery. HIFU enables transcutaneous tumor treatment without making a single incision, thus avoiding blood loss and the risk of infection. Also, HIFU therapy may be performed without the need for anesthesia, thereby reducing surgical complications and cost. Most importantly, these treatments may be performed on an outpatient basis, further reducing health care cost, while increasing patient comfort.

[0008] The use of HIFU for the destruction of tumors is a relatively new technique. The first clinical trials were performed on patients with hyperkinetic and hypertonic disorders (symptoms of Parkinson's disease). HIFU was used to produce coagulation necrosis lesions in specific complexes of the brain. While the treatment was quite successful, monitoring and guidance of the HIFU lesion formation was not easily achieved (N. T. Sanghvi and R. H. Hawes, "High-intensity focused ultrasound," *Gastrointestinal Endoscopy Clinics of North America*, vol. 4, pp. 383-95, 1994). The problem has been that the high energy therapeutic wave introduces a significant amount of noise into an ultrasound imaging signal employed to monitor the treatment site, making simultaneous imaging and treatment difficult. Indeed, the high energy of the HIFU can completely overwhelm conventional ultrasonic imaging systems. However, the advancement of imaging modalities has provided grounds for renewed research and development of HIFU-based tumor treatment methods. In general, current methods involve the use of discrete imaging and therapeutic steps, i.e., a treatment site is first imaged, therapy is applied, and the treatment site is again imaged. The therapeutic transducer is de-energized during the imaging process to eliminate the noise it would otherwise produce. However, the time required for carrying out each of these discrete steps has prevented the significant potential of HIFU from being fully realized, since real-time guidance and monitoring of HIFU has not been achieved.

[0009] Two HIFU-based systems have been developed for the treatment of benign prostatic hyperplasia (BPH) in humans (E. D. Mulligan, T. H. Lynch, D. Mulvin, D. Greene, J. M. Smith, and J. M. Fitzpatrick, "High-intensity focused ultrasound in the treatment of benign prostatic hyperplasia," *Br J Urol*, vol. 70, pp. 177-80, 1997). These systems are currently in clinical use in Europe and Japan, and are

undergoing clinical trials in the United States. Both systems use a transrectal HIFU probe to deliver 1,000-2,000 W/cm² to the prostate tissue through the rectum wall. No evidence of damage to the rectal wall has been observed during a rectoscopy, performed immediately after HIFU treatment (S. Madersbacher, C. Kratzik, M. Susani, and M. Marberger, "Tissue ablation in benign prostatic hyperplasia with high intensity focused ultrasound," *Journal of Urology*, vol. 152, pp. 1956-60; discussion 1960-1, 1994). Follow-up studies have shown decreased symptoms of BPH (i.e., increased urinary flow rate, decreased post-void residual volume, and decreased symptoms of irritation and obstruction; see S. Madersbacher, C. Kratzik, N. Szabo, M. Susani, L. Vingers, and M. Marberger, "Tissue ablation in benign prostatic hyperplasia with high-intensity focused ultrasound," *European Urology*, vol. 23 Suppl 1, pp. 39-43, 1993). In this prior art use of HIFU, ultrasound imaging is employed to obtain pre- and post-treatment maps of the prostate and the treatment area. Significantly, the noise induced in the imaging signal by the HIFU prevents real time imaging of the treatment site. Therefore, strict imaging requirements, such as no patient movement during the entire procedure (thus, the need for general or spinal anesthesia), limit the performance of these systems. It should be noted that respiration alone can result in sufficient patient movement so that the HIFU is no longer targeted as precisely as would be desired. Especially where the treatment site is adjacent to critical internal structures that can be damaged, the lack of real time imaging is a significant drawback to an otherwise potentially very useful treatment methodology.

[0010] HIFU has also been studied for the de-bulking of malignant tumors (C. R. Hill and G. R. ter Haar, "Review article: high intensity focused ultrasound—potential for cancer treatment," *Br J Radiol*, vol. 68, pp. 1296-1303, 1995). Prostate cancer (S. Madersbacher, M. Pedevilla, L. Vingers, M. Susani, and M. Marberger, "Effect of high-intensity focused ultrasound on human prostate cancer in vivo," *Cancer Research*, vol. 55, pp. 3346-51, 1995) and testicular cancer (S. Madersbacher, C. Kratzik, M. Susani, M. Pedevilla, and M. Marberger, "Transcutaneous high-intensity focused ultrasound and irradiation: an organ-preserving treatment of cancer in a solitary testis," *European Urology*, vol. 33, pp. 195-201, 1998) are among the cancers currently being investigated clinically for potential treatment with HIFU. An extensive clinical study to extracorporeally treat a variety of stage 4 cancers is underway in England (A. G. Visioli, L. H. Rivens, G. R. ter Haar, A. Horwich, R. A. Huddart, E. Moskovic, A. Padhani, and J. Glees, "Preliminary results of a phase I dose escalation clinical trial using focused ultrasound in the treatment of localized tumors," *Eur J Ultrasound*, vol. 9, pp. 11-8, 1999). The cancers involved include prostate, liver, kidney, hipbone, ovarian, breast adenoma, and ocular adenoma. No adverse effects, except one case of skin burn have been observed. Significantly, none of these studies has addressed the noise issue preventing the real time imaging of HIFU treatment.

[0011] U.S. Pat. No. 5,471,988 teaches the combination of a HIFU therapy transducer and an imaging transducer on the same probe. This patent points out that one of the problems with the prior art has been obtaining scanning data in conjunction with the therapeutic operation of the probe, due to the noise that the therapeutic wave introduces into the imaging signal. The reference notes that a problem with non-simultaneous imaging is that in the time frame between

when the image was last seen, and when the therapy transducer is energized, it is possible that the probe will move relative to a target area. Thus, the therapeutic energy may be applied to an area that is not the desired target. The patent teaches that it is desirable for the therapy and imaging transducers operate at different frequencies, e.g., 12 MHz for the imaging transducer and less than 2 MHz for the therapeutic transducer. It is also suggested that incorporating noise reduction circuitry in the imaging system can help to reduce the impact of the interfering noise. Unfortunately, it has been determined that this approach does not work as effectively as would be desired.

[0012] U.S. Pat. No. 5,769,790 describes another combination probe that includes transducers for both ultrasonic imaging and treatment. This patent teaches that prior to the delivery of therapy, verification of the focal point of the therapeutic wave is needed and advocates energizing the therapy transducer at a relatively low power level and using the imaging transducer to detect the low power ultrasound waves produced by the therapy transducer that are reflected from the target site. This technique provides a B-mode image where the only area in the image to be significantly illuminated is the focus of the therapy transducer. The image frame can then be interleaved with or super imposed on a normal B-mode image frame where both transmit and receive functions are performed using the imaging transducer. Once the focal point of the therapy transducer has been verified in this manner, therapy can be delivered by applying higher power, longer duration excitation to the therapy transducer. Significantly, the '790 patent does not teach the simultaneous scanning of the treatment area with the ultrasonic signal transmitted by the imaging transducer while the therapy transducer is operational, nor does the '790 patent discuss how the noise problem can be addressed.

[0013] U.S. Pat. No. 5,895,356 is directed to a method and apparatus optimized for the treatment of diseases of the prostate. This reference teaches that the echogenicity of tissue heated to over 60° C. changes so that when imaged using an ultrasonic imaging transducer, a bright spot appears in the viewing field, and that this echogenicity is transient (it fades with time). The patent also teaches storing the location of this region of higher echogenicity in a memory of an imaging system and superimposing the known focal point of the therapeutic transducer on the display of the imaging system, so that the therapeutic transducer can be focused on an area of interest prior to energizing the therapeutic transducer. The patent teaches imaging using low power ultrasound, focusing using the known focal point, ceasing the imaging, applying a higher power ultrasound therapy, ceasing the therapy, and then using low power ultrasound to generate an image of the area just treated. Significantly, the patent does not discuss how noise produced by the simultaneous operation of imaging and therapeutic ultrasound can be reduced.

[0014] While the prior art has recognizes the advantages that real time imaging can provide, a suitable method of achieving such imaging has not been described. It would be desirable to provide a method in which simultaneous imaging and therapy can be achieved in real time without a noise signal degrading the image quality of the treatment site.

[0015] Furthermore, there are many medical conditions that could benefit from simultaneous treatment and imaging

using HIFU. In particular, it appears that the treatment of gynecological and obstetrical disorders could be significantly enhanced. For example, uterine fibroids, which are benign tumors of the uterus and are found in more than half of all women, could be treated using an image-guided HIFU therapy system. Approximately 30% of all hysterectomies are related to these uterine fibroids. Current treatment methods for uterine fibroids include both drug therapy and surgery. Drug therapy has virtually a 100% rate of tumor reoccurrence once the drug therapy has stopped, and the drug therapy itself includes numerous negative side effects. The rate of reoccurrence is significantly less (about 15%) for the surgical therapy, though the surgical procedure is invasive, requiring a significant recovery period, and involves significant risks, such as blood loss, damage to related organs, and the ever present risk of infection. It is estimated that uterine fibroid procedures in the United States alone account for 1.2 to 3.6 billion dollars in annual medical costs.

[0016] Thus, it would be desirable to develop simultaneous or real time imaging and therapeutic ultrasound methods and apparatus. Initially, such methods and apparatus might be optimized for the treatment of uterine fibroids, and other gynecological and obstetrical disorders. Such treatment is expected to compare favorably with the costs for the current drug related therapy for the treatment of uterine fibroids and should compare favorably with the higher success rate of the current surgical procedures, but without the attendant risks.

SUMMARY OF THE INVENTION

[0017] In accord with the present invention, a method is defined for using ultrasound to simultaneously image a target area and to provide therapy to a treatment site within the target area in real time. The method employs a scanning ultrasonic transducer system adapted to scan a target area and to provide imaging data for the target area, a processor adapted to manipulate the imaging data, a display capable of providing a visual representation of the imaging data to a user to produce a displayed target area, and a therapeutic ultrasonic transducer system adapted to provide pulsed waves of HIFU to the treatment site within the target area.

[0018] The method includes the steps of scanning the target area to generate the imaging data, and displaying a visual representation of the imaging data. A treatment site is selected from within the displayed target area; and the therapeutic ultrasonic transducer system is energized to produce the therapeutic waves. Synchronization of the therapeutic ultrasonic transducer system relative to the scanning ultrasonic transducer system is adjusted such that any noise within the imaging data arising from the therapeutic waves is shifted away from the image of the treatment site. Thus, a noise-free image of the treatment site is provided.

[0019] In one embodiment, the therapeutic ultrasonic transducer system is initially energized at a level that is not energetic enough to produce a therapeutic effect at the treatment site, but is sufficiently energetic to produce a change in the echogenicity of tissue at the treatment site. This change in echogenicity is detected by the scanning ultrasonic transducer system, so that the focal point of the therapeutic ultrasonic transducer system is clearly displayed, enabling the therapeutic ultrasonic transducer system to be focused at a desired position for the treatment site. Once

properly focused, the energy level of the pulsed therapeutic wave is increased to a therapeutic level that is sufficiently energetic to produce a desired therapeutic effect.

[0020] In addition to monitoring for changes in the treatment site, the rest of the target area can be monitored to detect any changes to any non-treatment site area due to the HIFU. Such a change is undesirable, and when noticed, the therapeutic ultrasonic transducer system can be de-energized to prevent further changes to non-treatment site areas, even if the desired therapeutic effect has not yet been achieved at the treatment site.

[0021] Preferably, the processor is capable of manipulating the imaging data by effecting scan conversion processing, color flow processing, Doppler processing, B-mode processing or M-mode processing. In one embodiment, the three-dimensional (3D) location of the previously treated sites are stored and appear on the display.

[0022] In one preferred embodiment, the target area is the reproductive system of a mammalian female, and the desired therapeutic effect is applied to a uterine fibroid, an endometrial polyp, a follicular cyst, a polycystic ovary, a dermoid cyst, a corpus luteum cyst, an ectopic pregnancy, a cornual pregnancy, a multifetal pregnancy, a uterine malformation, an endometrial hyperplasia, an adenomyosis condition, and endometriosis condition, or an excessive bleeding condition. The treatment of disorders of the female reproductive system using the method of the present invention can be achieved by positioning the scanning ultrasonic transducer system and the therapeutic ultrasonic transducer system adjacent to the female reproductive system. Vaginal, rectal, abdominal, and laparoscopic approaches are contemplated. Accordingly, probes adapted for use in the vaginal canal and the rectum are also defined. Preferably, these probes incorporate both the scanning ultrasonic transducer system and the therapeutic ultrasonic transducer system. The methods include the step of inserting the probe into the appropriate cavity, and advancing the probe until the probe is adjacent to a target area before energizing the scanning ultrasonic transducer system. The focal point of the HIFU is positioned on the pathologic tissue.

[0023] In further embodiments using the above-described probes, the step of energizing the therapeutic ultrasonic transducer system generates frequencies within the range of 0.5 MHz to 10 MHz. An even more preferred range for the therapeutic ultrasonic transducer system is 1 MHz to 3.5 MHz.

[0024] In one embodiment, the therapeutic ultrasonic transducer system includes a phased array that enables the focal point of the therapeutic ultrasonic transducer system to be effectively enlarged. In another embodiment, the therapeutic ultrasonic transducer system comprises a vibrating element that is energized to cause a focal point of the therapeutic ultrasonic transducer system to be varied. The step of energizing the vibrating element causes the therapeutic ultrasonic transducer system to vibrate with a frequency in the range of 1 to 5 Hz, thereby avoiding the heating of tissue not associated with the treatment site in the unfocused regions of the HIFU beam. Alternately, the vibrating element causes the therapeutic ultrasonic transducer system to vibrate with a frequency in the range of 10 to 50 Hz, thereby increasing an amount of energy applied to the treatment site, while avoiding undesired cavitation effects.

[0025] The method enables HIFU to be used to cause the cauterization of tissue at the treatment site for arresting bleeding, preventing bleeding, or causing tissue necrosis. The HIFU can also be used to cause the necrosis of tissue at the treatment site by cavitation or thermal effects, or to ablate tissue at the treatment site.

[0026] Another aspect of the present invention is a method for treating a tumorous growth by damaging only selected regions within the tumorous growth. The steps of the method involve using the scanning ultrasonic transducer system to produce an image of the target area on the display as a visual representation of the target area. A selected region from within the tumorous growth is then selected as a treatment site.

[0027] The therapeutic ultrasonic transducer system is focused on the selected region until the desired level of damage is obtained. A different region within the tumorous growth is selected; and the steps are repeated until a desired pattern of damaged areas has been formed in the tumorous growth. After waiting a period of time sufficient to allow the macrophagic processes to remove necrotic tissue from the damaged areas, the treatment is repeated, until the tumorous growth is substantially destroyed.

[0028] Another aspect of the present invention is directed to a system for simultaneously imaging and applying treatment using ultrasound. The system includes elements that carryout functions generally corresponding to the steps of the methods discussed above.

BRIEF DESCRIPTION OF THE FIGURES

[0029] The foregoing aspects and many of the attendant advantages of this invention will become more readily appreciated as the same becomes better understood by reference to the following detailed description, when taken in conjunction with the accompanying drawings, wherein:

[0030] FIGS. 1A-1C respectively illustrate ultrasonic images generated during the simultaneous use of ultrasound for imaging and therapy according to the prior art, the pulsing of the HIFU in a conventional scanned image, and the synchronized pulsing of the HIFU and the scan image so as to shift the noise away from a displayed treatment site;

[0031] FIG. 2 is a block diagram illustrating the components of a system capable of the simultaneous use of ultrasound for imaging and therapy, in accord with the present invention;

[0032] FIGS. 3A(1)-3D(4) illustrate timing and synchronization patterns that enable the simultaneous use of ultrasound for imaging and therapy;

[0033] FIG. 4 illustrates yet another timing and synchronization pattern for synchronizing the HIFU and imaging scans;

[0034] FIG. 5A is a schematic view of individual external imaging and therapeutic ultrasonic transducers being used for the simultaneous imaging and treatment of a tumor in a female reproductive system, and FIG. 5B illustrates an ultrasonic image that would be thus generated;

[0035] FIG. 6 is a schematic view of a vaginal probe that includes both imaging and therapeutic ultrasonic transducers

being used for the simultaneous imaging and treatment of a tumor in a female reproductive system;

[0036] FIG. 7 is a schematic view of a rectal probe that includes both imaging and therapeutic ultrasonic transducers being used for the simultaneous imaging and treatment of a tumor in a female reproductive system;

[0037] FIG. 8 is a schematic view of a prior art vaginal probe that includes an imaging transducer;

[0038] FIG. 9 is a schematic view of the distal end of a vaginal probe and FIG. 9B is a HIFU module adapted to be used in conjunction with the vaginal probe;

[0039] FIG. 10 is a schematic view of a HIFU module mounted onto the distal end of a prior art vaginal probe;

[0040] FIG. 11 is a schematic view of a combination HIFU module and prior art vaginal probe, and an ultrasonic image produced thereby in which the focal point of the HIFU module is displayed in a noise-free area of the image, in accord with the present invention;

[0041] FIG. 12 is a schematic view of a second embodiment of a HIFU module combined with a prior art vaginal probe;

[0042] FIG. 13 is a cross-sectional view of the second embodiment of the combination HIFU module and prior art vaginal probe, including a chamber in fluid communication with both the imaging and therapeutic transducers;

[0043] FIG. 14 is a schematic view of the second embodiment of the combination HIFU module and prior art vaginal probe, including the fluid filled chamber and the wave patterns of both the imaging and therapeutic transducers;

[0044] FIG. 15 is a schematic view of a third embodiment of a HIFU module combined with the prior art vaginal probe, including a chamber in fluid communication with only the therapeutic transducer;

[0045] FIG. 16 is a schematic view of therapeutic and imaging transducers integrated into a vaginal probe that includes a paddle-shaped distal end;

[0046] FIG. 17 is a side elevational view of the integrated probe of FIG. 16 illustrating how a position of the paddle-shaped head can be varied around a pivot joint;

[0047] FIG. 18 is a schematic view of phased array therapeutic and imaging transducers of the integrated probe of FIG. 16, in which the imaging transducer is steerable, and the focal point of the therapeutic transducers is variable;

[0048] FIG. 19 is a schematic view of a different embodiment of a paddle-headed integrated probe similar to that of FIG. 16, in which the orientation of the imaging transducer has been shifted by 90°, thus shifting the scanning field by 90°;

[0049] FIG. 20 is a schematic view of a different embodiment of a paddle-headed integrated probe similar to that of FIG. 18, in which the therapy transducer is steerable in the same plane as the imaging transducer;

[0050] FIG. 21 is a schematic view of phased array therapeutic and imaging transducers of an integrated probe in which both the imaging transducer and the therapy transducer are steerable along both their longitudinal and latitudinal axes; and

[0051] FIG. 22 is a schematic block diagram of a 3D imaging and HIFU therapy system that enables the HIFU therapy to be applied at selected treatment sites in a 3D image of a target area.

DESCRIPTION OF THE PREFERRED EMBODIMENT

[0052] As noted above in the Background of the Invention, the prior art has recognized that real time imaging of therapeutic HIFU would be beneficial in a number of treatment methodologies. From a practical standpoint this is not proven easy to do, because the HIFU used for therapy completely saturates the signal provided by the imaging transducer. One analogy that might help to make this problem clear relates to the relative intensities of light. Consider the light coming from a star in the evening sky to be equivalent to the low power imaging ultrasound waves that are reflected from a target area toward the imaging transducer, while the light from the sun is equivalent to the HIFU generated by the therapy transducer. When the sun is out, the light from the stars is completely overwhelmed by the light from the sun, and a person looking into the sky is unable to see any stars, because the bright light from the sun completely masks the dim light coming from the stars. Similarly, the HIFU emitted by the therapy transducer completely overwhelms the ultrasonic waves produced by the imaging transducer and any ultrasonic image generated is completely saturated with noise caused by the HIFU from the therapeutic transducer.

[0053] FIG. 1A illustrates an ultrasound image 10 in which a scanned field 12 is completely obscured by noise 14, caused by the simultaneous operation of an imaging pulse and a HIFU wave (neither shown). In ultrasound image 10, a clinician may desire to focus the HIFU wave on a treatment site 18. However, because noise 14 completely saturates scanned field 12, it is impossible to accurately focus the HIFU wave onto treatment site 18. If the therapy transducer is completely de-energized, noise 14 is eliminated from the scanned field. However, under these conditions, the focal point of the HIFU wave will not be seen, and thus, the HIFU wave cannot be accurately focused on treatment site 18. While some change in echogenicity at the HIFU focal point will persist for a time even after the HIFU wave is gone, any change in a position of the therapy transducer (or treatment site 18), would not register until the therapeutic transducer is re-energized, thus the HIFU wave is cannot be focused in real time.

[0054] Some prior art systems have included a targeting icon in an ultrasound image to indicate where the known focal point of a specific HIFU transducer would be located in a scanned image. While this icon may be helpful in determining whether the HIFU was previously focused, it still did not enable a clinician to observe real-time results. Once the HIFU therapeutic transducer was energized, the scanned ultrasound image was completely saturated with noise and the clinician could not monitor the progress of the treatment without again de-energizing the HIFU therapeutic transducer.

[0055] FIG. 1B illustrates one technique in which the amount of noise disrupting the ultrasound image is reduced. In FIG. 1B, the HIFU wave generated by the therapeutic transducer has been pulsed. This technique produces an

ultrasound image 20, in which the location of noise 24 in a scanned field 22 is a function of the interference between the pulsed HIFU wave generated by the therapy transducer and the ultrasonic imaging pulses generated by the scanning transducer. In FIG. 1B, noise 24 substantially masks a treatment site 28. This result would not occur in all cases, as to an observer noise 24 would move across scanned field 22 as the interference between the HIFU waves and the imaging pulses varied in time. Pulsing of the HIFU wave alone would thus allow the clinician to view a noise-free image of the treatment site only when noise 24 was randomly shifted to a different part of scanned field 22, away from the treatment site. However, such pulsing alone generates an image that is extremely distracting to a clinician, as noise 24 flickers across scanned field 22, making it difficult to concentrate and difficult to consistently determine where the focal point of the HIFU wave is relative to the treatment site, in real time.

[0056] FIG. 1C illustrates an ultrasound image 30 in which a HIFU wave from a therapy transducer has been both pulsed and synchronized with respect to the ultrasonic imaging pulses from an imaging transducer, to ensure that noise 34 does not obscure a treatment site 38. In ultrasound image 30 noise 34 has been shifted to a location within a scanned field 32 that is spaced apart from treatment site 38, by selectively adjusting both the pulsing and the synchronization of the HIFU wave. Preferably, noise 34 is shifted completely away from treatment site 38, thus allowing the clinician a noise-free stable image of treatment site 38 that clearly shows the location of the focal point of the HIFU wave relative to the treatment site. Thus, the HIFU wave can be focused in real time onto treatment site 38, and a clinician can, in real time, view the therapeutic effects of the HIFU wave on treatment site 38. It will be apparent that a clinician can de-energize the therapeutic transducer, thereby ceasing the generation of the HIFU wave, as soon as a desired therapeutic effect has been achieved at the treatment site. In this manner, undesired effects on non target tissue can be minimized.

[0057] The terms "therapeutic transducer," "HIFU transducer," and "high intensity transducer," as used herein and in the claims that follow all refer to a transducer that is capable of being energized to produce ultrasonic waves that are much more energetic than the ultrasonic pulses produced by an imaging transducer, and which can be focused or directed onto a discrete location, such as a treatment site in a target area. However, not all ultrasonic waves produced by such a transducer are at a high intensity in at least one embodiment of the present invention, as will be explained below.

[0058] FIG. 2 illustrates a block diagram of an embodiment of the present invention that synchronizes the image and HIFU waves required for the simultaneous imaging and therapy in real time. An ultrasound imaging machine 40 is an ultrasound imaging system of the type that is well known to those of ordinary skill in the art and can be purchased from vendors such as ATL Inc., of Bothell, Wash. An imaging probe 44 that is also of a type well known to those of ordinary skill in the art is connected to ultrasound imaging machine 40 via a cable 42. Imaging probe 44 generates ultrasonic imaging pulses that propagate to the target area, are reflected from structure and tissue within the body, and are received by the imaging probe. The signal produced by

the imaging probe in response to the reflected ultrasound waves is communicated to the ultrasound imaging machine through cable 42 and processed to provide a visual representation of the structure and tissue that reflected the ultrasonic imaging pulses. An imaging beam sector 46 from imaging probe 44 is identified in the Figure by dash lines. Also included in the present invention is a therapeutic transducer 60. When excited, this therapeutic transducer generates HIFU waves that are focused at a particular point of interest, i.e., a treatment site within a patient's body. In FIG. 2, the path of a HIFU beam 62 is indicated by dotted lines. HIFU beam 62 narrows to a focal point 64. Those of ordinary skill in the art will recognize that position of focal point 64 relative to therapeutic transducer 60 is a function of the geometry of the therapeutic transducer and will normally depend upon the application. For example, a therapeutic transducer that will be used to apply HIFU therapy to the uterus of a patient from within the vaginal canal (see FIG. 6) will have a different optimum focal point than a therapeutic transducer used to apply treatment to the uterus from outside a patient's body (see FIG. 5).

[0059] It should be noted that ultrasound imaging machine 40 differs from prior art systems in several ways, including its inclusion of a synchronization output signal 48. Preferably, ultrasound imaging machine 40 is modified to enable synchronization output signal 48 to be obtained. Because such a synchronization output signal has not been required for prior art ultrasonic imaging applications, provision of a synchronization output signal has generally not been made in prior art ultrasound imaging machines. If a prior art imaging machine that has not been modified to provide synchronization output signal 48 is used, the synchronization output signal can instead be derived from the ultrasonic imaging signal conveyed by cable 42.

[0060] Synchronization output signal 48 is supplied to a synchronization delay circuit 50. Synchronization delay circuit 50 enables the user to selectively vary the initiation of each HIFU wave with respect to each sequence of ultrasonic imaging pulses that are generated to form an ultrasonic image. Referring to FIG. 1C, delay 50 enables a user to vary the position of noise 34 in scanned field 32, so that the noise is moved away from treatment site 38, to a different portion of scanned field 32. The user is thus provided a noise-free image of treatment site 38.

[0061] A HIFU duration circuit 52 is used to control the duration of the HIFU wave. A longer duration HIFU wave will apply more energy to the treatment site. Generally, the more energy that is applied to a treatment site, the faster a desired therapeutic effect will be achieved. However, it should be noted that if the HIFU wave is too long, the duration of noise 34 as shown in ultrasound image 30 will increase and can extend into the next ultrasound imaging pulse to obscure treatment site 28, or may completely obscure ultrasound image 30, generating a display very similar to ultrasound image 10 in FIG. 1A. Thus, the user will have to selectively adjust HIFU duration circuit 52 to obtain a noise-free image of treatment site 38, while providing a sufficient level of energy to the treatment site to effect the desired therapeutic effect in an acceptable time.

[0062] A HIFU excitation frequency generator 56 is used to generate the desired frequency for the HIFU wave, and a power amplifier 58 is used to amplify the signal produced by

the HIFU excitation frequency generator to achieve the desired energy level of the HIFU wave; power amplifier 58 is thus adjustable to obtain a desired energy level for the HIFU wave. Optionally, a stable synchronization signal generator 66 can be used to synchronize the HIFU wave to the imaging ultrasonic wave, instead of using synchronization output signal 48 from ultrasound imaging machine 40. Stable synchronization signal generator 66 can be used to provide a stable synchronizing pulse to initiate the HIFU wave, and the timing of this stable synchronizing pulse can be selectively varied until a noise-free image of the treatment site has been obtained. A drawback of using stable synchronization signal generator 66 instead of synchronization output signal 48 is that any change in the timing of the ultrasound imaging pulses, such as is required to scan deeper within tissue, will require an adjustment to stable synchronization signal generator 66 that would not be required if synchronization output signal 48 were used. The processor will be able to automatically find a stable synchronization signal using information from the movement of the noise.

[0063] FIGS. 3A(1)-3D(4) and FIG. 4 provide further detail for the synchronization and pulsing features of the present invention. FIG. 3A(1) shows ultrasound imaging pulses 46a produced by imaging machine 40 and imaging probe 44 that are used to acquire an ultrasound image of a target area (such as ultrasound image 30 of FIG. 1C). A synchronization pulse 48a is shown in FIG. 3A(2). It should be noted that synchronization pulse 48a is illustrated as occurring before the generation of ultrasound imaging pulses 46a; however, the timing of synchronization pulse 48a relative to the imaging pulses is not critical, so long as it is stable. Synchronization pulse 48a merely establishes a timing reference point, from which a delay 50a (shown in FIG. 3A(3)), used for the initiation of the HIFU wave, is set such that noise from the HIFU wave in an ultrasonic image generated by imaging pulses 46a is shifted away from the image of the treatment site. The delay 50a is not fixed, and it is adjusted by the user until a noise-free image of the treatment site is obtained.

[0064] A HIFU duration 52a, shown in FIG. 3A(4), determines the duration of the HIFU wave. HIFU duration 52a may be very brief, as shown in FIG. 3A(4), or extended, as shown in FIGS. 3B(4) and 3C(4). An increase in the duration of the HIFU wave will cause a greater portion of an ultrasound image to be obscured by noise, and may cause the HIFU wave to interfere with the image of the treatment site. In FIG. 3A(4), delay 52a is very short, and the resulting noisy region in the ultrasound image will be very small. However, a short duration HIFU wave means a correspondingly small amount of HIFU energy will be delivered to the treatment site, thus increasing the length of the treatment. A clinician must balance the length of HIFU duration needed to maintain a noise-free image of the treatment site against the time required to complete the therapy. It should be noted that as an alternative to using HIFU duration 52a to control the HIFU excitation frequency generator to variably set the duration of the HIFU wave, the HIFU excitation frequency generator itself could be adjusted to control the duration.

[0065] FIGS. 3B(1)-3C(4) similarly illustrate timing patterns that incorporate different settings for the delay relating to the initiation of the HIFU wave (setting 50b in FIG. 3B(2), and setting 50c in FIG. 3C(2)) and delay relating to the duration of the HIFU wave (setting 52b in FIG. 3B(3),

and setting **52c** in **FIG. 3C(3)**). **FIGS. 3D(1)-3D(4)** illustrate a timing pattern that enables a longer duration HIFU wave (thus more energy applied to the treatment site) to be used, while still enabling a noise-free image of the treatment site to be generated. In **FIG. 3D(1)**, ultrasound imaging pulses **46b** and **46c** appear to be much shorter than in **FIGS. 3A(1), 3B(1)** and **3C(1)**, but actually are of the same duration, as the scales of **FIGS. 3D(1)-3D(4)** have been significantly increased. Synchronization pulse **48a** of **FIG. 3D(2)** is obtained and used as described above. A delay **50d** in **FIG. 3D(3)** is set to obtain a noise-free image of the treatment site, also as described above; however, as will be clarified below, not all of these synchronization pulses govern the image that is produced, as the delay **52d** dominates. The significant difference between **FIGS. 3D(1)-3D(4)** and **FIGS. 3A(1)-3C(4)** is that delay **52d** has been significantly increased in **FIG. 3D**, such that a very long burst of HIFU energy is emitted, almost to the point of continuous emission. Here, the noise-free imaging occurs only every seventh image, during interrogation wave **46c**. By adjusting delay **52**, more or fewer images will be interfered with, and therefore, various duty cycle lengths for HIFU exposure can be accommodated. It should be noted as the number of images interfered with by the HIFU wave increases (here, 6 out of 7), the resulting image of the target area will arguably provide less real-time feedback. However, the actual time between visible images of the treatment site may be so short as to appear to occur in real time. But, at very high settings for the HIFU duration (such as to cause the HIFU wave to interfere with 99 out of 100 images of the treatment site), the advantages associated with real-time imaging of the treatment site are diminished. Thus, the HIFU duration will preferably not be set so high as to negate the benefits of real-time imaging of the treatment site and its ability to provide the clinician with immediate feedback concerning the effect of the therapy on the treatment site.

[0066] **FIG. 4** illustrates another timing sequence that shows the relationships between ultrasound imaging pulses **46d**, a synchronization pulse **48b**, a delay **50e**, and a HIFU duration **52e**. In this timing sequence, synchronization pulse **48b** occurs during the ultrasound imaging pulses **46d**, rather than preceding the ultrasound imaging pulses, as shown in **FIGS. 3A-3D**. As noted above, the position of each synchronization pulse **48b** relative to the ultrasound imaging pulses is not critical, as delay **50e** is adjusted to shift the noise away from the image of the treatment sight. Again, the duration of the HIFU wave (and thus, the energy applied to the treatment sight) is varied either by adjusting delay **52e**, as shown in **FIG. 4**, or by adjusting the HIFU excitation generator.

[0067] Imaging of HIFU Focal Point

[0068] It will often be important for a clinician to be able to confirm that the focal point of a HIFU transducer is directed at a desired treatment site before initiating HIFU therapy. It has been determined that if the energy level of a HIFU transducer is reduced to a level less than a level that would cause any damage to tissue, the focal point of the HIFU transducer will still be evident within the target area displayed in the image developed from the reflected ultrasound signal produced and received by the ultrasound imaging transducer. The focal point will appear as a bright spot in the displayed image and will rapidly fade over time. Thus, it is possible for a clinician to move the HIFU transducer as

necessary to shift the focal point to a desired treatment site in the target area being imaged by the ultrasound imaging transducer and to see the focal point in the image as a bright spot that moves as the position of the HIFU transducer is changed. Only after the focal point is positioned on a desired treatment site will the clinician increase the energy of the ultrasound pulses produced by the HIFU transducer to a level sufficient to achieve the desired therapeutic effect, e.g., to a level sufficient to necrose tissue, or cause hemostasis. It should be noted that the ultrasound imaging transducer is not receiving the ultrasound signal produced by the HIFU transducer that is reflected by the tissue, but instead, is likely imaging the effect of the change in echogenicity of the tissue caused by the relatively low energy ultrasound burst produced by the HIFU transducer. This technique can be used with any of the HIFU transducers discussed below.

[0069] A further advantage of the preceding technique for imaging the focal point of a HIFU transducer can be achieved by storing the image of each successive treatment site, which will appear as a bright area in the image produced by the ultrasound imaging transducer system. For example, a storage type display, of the type readily available, can be used for this purpose. By storing the image of each treatment site to which the HIFU therapy has previously been administered during a current session, it is possible for a clinician to target spaced-apart treatment sites in the target area, thereby ensuring the HIFU therapy has been administered to all of the desired portion of a tumor or other structure in the patient's body. Since each previous treatment site will be visible in the image, it will be apparent that a desired pattern of treatment sites can readily be laid down over the tumor or other structure of interest. The change in echogenicity caused by a relatively high energy therapeutic HIFU wave will be brighter and persist longer in the display, enabling the clinician to easily distinguish between a current prospective focus point for the next treatment site (produced using the low energy pulse) and the previous treatment sites to which the HIFU therapy has already been administered.

[0070] 3D Imaging System

[0071] In **FIG. 22**, a block diagram is illustrated for a system **200** that enables imaging of a target area in 3D and storing of the locations of treatment sites to which the HIFU therapy has been administered in the 3D image as a HIFU therapy session proceeds. The system includes a 3D image data processor and display **202**, an image acquisition section **204**, a magnetic field sensor **206**, a magnetic field generator **208**, and 6D electronic processing circuitry **210**. The latter three components are employed to track the imaging target area and the HIFU focal point as they are redirected in the 3D space and are part of a six-dimensional (6D) measurement system (i.e., three spatial coordinates for the 3D orthogonal axes and three angles of rotation around these three orthogonal axes). A 6D measurement system is commercially available from Ascension Technology, Burlington, Vt. This 6D measurement system uses 6D electronic processing circuitry **210** and magnetic field generator **206** to produce time sequential orthogonally oriented magnetic fields covering a general area as indicated in the Figure by the dash line that encompasses the region of magnetic field. Magnetic field sensor **206** is mounted on a combined imaging and HIFU therapy probe **212** in a fixed manner relative to imaging and HIFU transducers **214**. The magnetic field sensor detects the magnetic field strength in 3D sequentially

produced by the magnetic field generator. The 6D electronic processing circuitry uses the information from the magnetic field sensor and the known magnetic fields that were produced to compute the 3D position and the three angular orientations around the three orthogonal axes of the magnetic field sensor (and thus, of the combined imaging and HIFU therapy probe) with respect to the magnetic field generator, yielding the 6D information. The 6D information is supplied to 3D image data processor and display **202** at a rate sufficient to enable movement of the magnetic field sensor to be tracked in the displayed 3D image of the target area. With information derived from calibrating system **200** with the imaging probe, the position of the target area and the HIFU transducer focal point can be related to a 3D spatial point, so long as magnetic field sensor **206** is within the range of the magnetic field produced by magnetic field generator **208**. 3D image data processor and display **202** also receive ultrasound image information from an ultrasound imaging machine **216** through image acquisition section **204**. It uses this information to develop and display 3D information. Ultrasound imaging machine **216** provide the synchronization signal to a HIFU control and electrical energy generating system **218**, as discussed above. The remaining component in **FIG. 22** is a physiological information acquisition section **220**, which enables synchronization of the imaging and HIFU therapy with physiological activity, such as respiration or cardiac activity (provided by an electrocardiogram system—not shown). Use of the physiological information avoids problems associated with movement of the patient's body due to physiological activity. For example, 3D imaging and HIFU therapy can be control so that they are implemented only at the end of expiration in the breathing cycle, since motion of the patient is more repeatable then than at mid inspiration. A physiological sensor such as a respiration detector (not shown), which is well known in the art, can provide the information for this section of the system.

[0072] As noted above, by storing the location of each of the treatment sites where HIFU therapy has been administered during a therapy session, a clinician will be able to determine where each successive treatment site should be targeted to achieve a desired pattern of HIFU therapy within a tumor or other region of interest. The bright spot in the 3D image showing the location of each previous treatment site greatly facilitates this targeting process and enables a desired pattern of HIFU therapy to be achieved with considerable accuracy.

[0073] By using the 3D display to view the progression of successive treatment sites, other types of therapeutic results can be achieved. For example, the HIFU therapy can be employed to create a plurality of lesions on blood vessels supplying blood to a tumor, cutting off the supply of nutrients and oxygen to the tumor provided by the blood supply. Thus, it is possible to destroy a tumor without directly using the HIFU therapy to destroy tumor tissue. The results of this technique are similar to those arising from the procedure referred to as "embolization," in which a clot-inducing material is introduced into the vessel using a small catheter, but the HIFU therapy can achieve the same result non-invasively and can treat vessels that are too small or otherwise not accessible to render treatment through a catheter. Embolization is a relatively new technique and has been used to treat a variety of conditions, including uterine fibroids. While the ability to store the location of previous

treatment sites so that they are shown on a displayed 3D image of the target area is not essential to this use of HIFU therapy, it will be evident that the display of the treatment sites used to create lesions in the vessels will facilitate this procedure. Further, it should be noted that using HIFU to occlude (or induce hemostasis in) the blood vessels that supply oxygen and nourishment to a structure within the body can be used in conjunction with other imaging techniques, such as CT, MRI, or angiography.

[0074] Another imaging technique that is likely to be useful to a clinician when using HIFU to create lesions in blood vessels is Doppler Flow imaging, which can be used to represent blood vessels supplying a structure with blood in one color, and blood vessels that remove blood from a structure in a second color. As those of ordinary skill in the art will readily recognize, the circulation of blood within these blood vessels either adds to or subtracts from the imaging wave, enabling blood vessels having blood flowing in opposite directions to be differentiated from one another.

[0075] A final imaging technique that will likely be beneficially employed by a clinician using HIFU to create a lesion in a blood vessel is the use of conventional ultrasound imaging contrast agents. Not only will the use of such agents provide the clinician with a more useful ultrasonic image, but it is anticipated that such agents may actually increase the effectiveness of the HIFU in producing the desired lesion.

[0076] Use of Anesthetic Agent to Enhance Image of Low Power HIFU at a Treatment Site

[0077] While operating a HIFU transducer at a substantially reduced power to determine the location of its focal point within a target area will produce a bright spot visible in the image, it may sometimes be desirable to enhance the visibility of the focal point in the image—in either a 2D or 3D image. The change in echogenicity of the tissue due to the administration of a relatively low power HIFU wave to the tissue is what enables the location to be seen in the image of the target area. However, it is believed that a substantially brighter spot showing where the HIFU wave (at low power) was focused can be achieved if an anesthetic agent other blood soluble agent having a relatively high vapor pressure has previously been administered to the patient. Use of such agents, which will readily vaporize when exposed to the slight elevated temperatures caused by low power ultrasound on tissue, should produce small bubbles at the focal point of the HIFU transducer. These bubbles will produce a substantially brighter spot in the ultrasound image and at an even lower energy level of the HIFU transducer than the spots produced by the low energy HIFU waves when no such agent has been administered to the patient. Reduction of the HIFU energy to an even lower level will further ensure that the focal point of the HIFU transducer can be seen in the ultrasound image produced by the imaging transducer without risk of damage to tissue that is not to be treated.

[0078] Advantage of Simultaneous, Real-Time Imaging

[0079] Major advantages to real-time imaging of therapeutic HIFU while it is being applied are: (1) the HIFU treatment can be stopped when a therapeutic produced lesion has grown to the point at which it begins to extend beyond the desired treatment site, and the HIFU focal point can then be repositioned to another treatment site and reactivated; (2)

the focal point of the HIFU wave can be observed in the image due to changes in the echogenicity of the tissue at the focal point, which are apparent in the images of the target area, providing an instant feedback that can enable a clinician to adjust the focal point onto a desired treatment site; (3) the HIFU focal point can be adjusted during the administration of the HIFU therapy to compensate for tissue movement within the patient's body due to breathing or for other reasons; (4) real-time visualization of a treatment site is very reassuring to the medical therapist, in confirming that the HIFU energy is being applied to the correct position (and that healthy tissue is not being damaged); (5) the combined imaging and therapeutic treatment can be accomplished much faster than in the past, when it was necessary to render treatment, stop the treatment, image the site, and then continue the treatment; and, (6) it enables the clinician to administer the HIFU therapy in a desired pattern of treatment sites so that, for example, a matrix of necrotic points in a tumor can be achieved to de-bulk the tumor without treating all of the tumor. Further details of how each of these advantages are achieved by the present invention are discussed below.

[0080] FIGS. 5-7 illustrate how a variety of different configurations of HIFU transducers and imaging transducers can be used to simultaneously provide real-time imaging and therapy to an internal treatment site within a patient's body. It is expected that HIFU therapy with real-time imaging can be beneficially employed to treat a variety of disease conditions. In particular, it is envisioned that conditions relating to the reproductive system of a mammalian female will particularly benefit from HIFU therapy with real-time imaging, as ultrasonic imaging itself is widely used in association with the female reproductive system. It is envisioned that HIFU therapy can be applied to a uterine fibroid, an endometrial polyp, a follicular cyst, a polycystic ovary, a dermoid cyst, a corpus luteum cyst, an ectopic pregnancy, a cornual pregnancy, a multifetal pregnancy, a uterine malformation, an endometrial hyperplasia, an adenomyosis condition, and endometriosis condition, or an excessive bleeding condition. The treatment of disorders of the female reproductive system using the method of the present invention can be achieved by positioning the scanning ultrasonic transducer system and the therapeutic ultrasonic transducer system adjacent to the female reproductive system. Vaginal, rectal, abdominal and laparoscopic approaches are contemplated.

[0081] In FIG. 5, both a HIFU transducer 102 and an imaging transducer 104 are disposed external to the patient's body. The reflected ultrasound waves received by imaging transducer 104 are used to generate an ultrasound image 100. In FIG. 5, the HIFU is being used to treat a tumor 110 on a uterus 111 of the patient. Imaging transducer 104 is positioned so that tumor 110 is clearly displayed in ultrasound image 100. Also visible in ultrasound image 100 is a cross section of a rectum 106. HIFU transducer 102 is being used to destroy tissue in tumor 110. The necrotic tissue is clearly visible as a lesion 112 in both the cross section of the body and in ultrasound image 100.

[0082] FIG. 6 illustrates an embodiment in which a HIFU transducer 102a and an imaging transducer 104a have been combined on a vaginal probe 109. Vaginal probe 109 has been inserted into a vaginal canal 108a and positioned to enable imaging transducer 104a to be used in generating an ultrasonic image of a tumor 110a. Once tumor 110a has been

located, HIFU transducer 102a is focused on a selected portion of tumor 110a to which the clinician desires to administer the HIFU therapy to generate a lesion 112a. The HIFU therapy is used to destroy the tumor by causing lesions of the blood vessels supplying oxygen and nutrients to the tumor, thereby generating a plurality of lesions similar to lesion 112a, so that the tumor withers away, or by destroying spaced-apart portions of the tumor. Particularly if the latter technique is used, the HIFU therapy will likely be repeated at intervals of several weeks. The time between successive therapy sessions enables macrophages in the patient's body to clear away or debride the necrotic tissue from the tumor so that it is reduced in size with each therapy session and eventually destroyed.

[0083] FIG. 7 illustrates a rectal probe 109a, which incorporates a combination of a therapy transducer 102b and an imaging transducer 104b. Rectal probe 109a has been inserted into a rectum 106b of the patient, and the imaging transducer is being used to locate a tumor 110b. Once tumor 110b has been located, therapy transducer 102b is focused on the desired portion of the tumor, and HIFU therapy is administered to a treatment site 112b, until the desired therapeutic effect is achieved.

[0084] FIGS. 9-19 provide details of preferred embodiments of probes that can be used to simultaneously provide imaging and therapy to a treatment site. It should be noted that the method of simultaneously imaging and providing treatment using ultrasound can be applied to different locations in or on a patient's body to treat a variety of medical conditions. One application of a preferred embodiment of the present invention is employed, by way of example, to provide simultaneous ultrasonic imaging and HIFU therapy of a uterine fibroid. However, it should be understood that the simultaneous imaging and therapy using the described method is not at all limited to the treatment of uterine fibroids, or even the treatment of gynecological or obstetrical disorders.

[0085] For an exemplary application of the present invention described below, a vaginal ultrasonic imaging probe is employed. Vaginal ultrasonic imaging probes are well known in the prior art. FIG. 8 illustrates one such prior art ultrasonic vaginal imaging probe, which is a Model C9-5 transvaginal probe available from ATL Inc. of Bothell, Wash. It is envisioned that several different types of HIFU transducers can be mounted onto the standard transvaginal imaging transducer probe to allow the simultaneous imaging and therapy of treatment sites related to the female reproductive system, in accord with the present invention.

[0086] Transducer and Probe Design for the Vaginal Application of HIFU to Treat Uterine Fibroids

[0087] As noted above, an exemplary application of the present invention is a vaginal probe incorporating both imaging and therapeutic transducers. As HIFU transducer design is a function of the location of the desired treatment site, the following discussion is useful in determining preferred design parameters for a vaginal probe combining imaging and therapeutic transducers optimized for applying HIFU therapy to uterine fibroids.

[0088] The relationship between the distance from the HIFU transducer to the focus (focal length) and the surface area of the aperture is well known to those of ordinary skill

in the art. For a circular aperture, the $j\#$ (or relative aperture) is defined as being equal to the "focal length divided by the diameter of the aperture". A low number is preferred, as this insures a highly focused beam, thereby minimizing any undesired effects of the HIFU beam on adjacent tissue. A preferred number is 1; but a number as high as 1.75 can be used, therefore a practical range is from 1-1.75. The lower the number, the tighter the focus, and the greater the intensity of the HIFU beam will be at the focus, with respect to the HIFU beam intensity at the surface of the transducer. This is important because a high intensity is required at the focal point to achieve a desired therapeutic effect in a short period of time. Conversely, moderate or low intensities are needed at the surface of the transducer, so that the HIFU beam generated at the surface of the transducer can pass through the tissue intermediate to the transducer surface and the focal point. This intermediate tissue is affected by the at this point unfocused HIFU beam as it passes through the intermediate tissue to the focal point. If the unfocused HIFU beam is of sufficiently low intensity, the effect of the unfocused HIFU beam on the intermediate tissue will be negligible. As the unfocused HIFU beam approaches the focal point, the intensity increases as the HIFU beam becomes more focused, until a sufficient intensity is obtained at the focal point to achieve a desired therapeutic effect. Generally, the effect a HIFU beam has on tissue is to heat the tissue (though HIFU can also have a mechanical effect on tissue via cavitation). Therefore a low intensity at the surface of the transducer is desired to minimize the heating of the intermediate tissue, while for successful treatment, the tissue at the focus must be heated much more rapidly in order to achieve therapeutic temperatures at the focus without undue heat build up in the intermediate tissue. Therefore, it is very important to know the maximum distance from the transducer that one desires to treat, to determine the maximum focal length required. At the same time, one must have an understanding of the largest size aperture that one can physically introduce into the vaginal tract.

[0089] Based on a review of obstetrical and gynecological literature, the applicants experience, and a study of duckbill speculums (medical devices used for the inspection of the vagina and cervix.), applicants have identified that the external opening of the vaginal canal generally has a circumferential dimension which ranges from of 10-12 cm. Since the vaginal entrance is longitudinal in nature, a probe having a distal end that is "paddle" or "spoon" shaped would be most beneficially employed. Practical transducer considerations require that the distal end of the probe (the logical point for mounting a therapeutic transducer) would be at least 0.5 cm thick, and that the widest portion of this "paddle" design would range from 4.5-5.5 cm. Since the vagina is a muscular structure that is quite strong, it can be stretched somewhat further, but this is uncomfortable for the patient. Therefore, it is preferred that the widest portion of the paddle range from 4.5-6 cm.

[0090] The design of a preferred focal length necessitated an analysis of where within the vaginal canal the probe will be positioned, and where uterine fibroids are likely to occur. Preferably the probe will be positionable in the vagina at the cervix. The vaginal fornices are potential spaces formed by folds within the vaginal canal around the cervix, extending 5-6 cm along the uterus. Therefore, near the cervix, the vaginal cavity has a larger space, allowing either a larger probe, or the manipulation of a smaller probe, to achieve

imaging and therapy of a desired site in the uterus. Based on a review of obstetrical and gynecological literature, the size range of uterine fibroids is from 1-15 cm, and the length of the uterus is approximately 5-6 cm. Therefore, a maximum focal length of about 20 cm would reach an entire fibroid located at the distal end of the uterus. Based on applicants' practical experience, it is anticipated that 20%, 35%, 50%, 75%, and 80% of all uterine fibroids will be within the respective distances of 4 cm, 6 cm, 8 cm, 10 cm and 12 cm respectively. From a cost/benefit point of view, a combination imaging and therapeutic vaginal probe needs to be able to treat at least 35% of uterine fibroids, and more preferably 50%. Therefore a preferred therapeutic transducer must be able to treat to a depth of at least 6 cm, and more preferably 8 cm.

[0091] The design of different embodiments of a vaginal probe including both imaging and therapeutic transducers is preferably limited to designs in which the largest circumferential dimension of the combination probe (measured generally transverse to a longitudinal axis of the probe) is about 10.6 cm, which is a nominal limit in size to enable the combination imaging and therapy transducer to be readily inserted through the vaginal opening and into the vaginal canal.

TABLE 1

Percentage of Fibroids Treatable for Relative Apertures with an area equivalent to a Circular Aperture			
Circular Aperture	Relative Apertures (f #)		
Diameter (cm)	1.25	1.5	1.75
4.5	<35%	>35%	50%
5	35%	<50%	<75%

[0092] Based on the calculations for a circular aperture and practical relative apertures, Table 1 provides information of the relative percentages of uterine fibroids that can be treated with a specific circular aperture. For a circular aperture of 4.5 cm, just less than 35% of all uterine fibroids can be treated with a relative aperture of 1.25. This then defines the minimum diameter of circular applicator as 4.5 cm, based on the design parameter of being able to treat 35% of uterine fibroids encountered. An elliptical aperture may also be used, in which case the minor axis represents the transverse direction, and thus the limiting dimension of a probe that can readily be inserted into the vagina. An elliptical surface area is larger than a circular surface if the minor axis length equals the diameter of the circular surface, and the major axis is greater than the minor axis. By using an elliptical surface, the focal length is greater than for a circular surface for a given relative aperture number. Therefore, with a two to one ratio of major to minor axis for example, a 9/4.5 ratio would exist for the minor axis chosen. Referring to Table 2, this is equivalent to a 6.5 cm diameter circular aperture. Looking at Table 1, for the equivalent of

a 6.5 cm diameter circular aperture, the percentage of fibroids that can be treated are 50%, <75% , and 75%, respectively, for relative apertures of 1.25, 1.5, and 1.75.

[0093] These results therefore dictate a vaginal probe with a HIFU transducer that has a distal end that is paddle or spoon shaped, with a minimum transverse dimension of 4.5 cm, and a maximum circumferential dimension (measured generally transverse to a longitudinal axis of the probe) of about 10.6 cm. No other devices cited in the prior art for use in other body orifices are suitable for a vaginal application of HIFU for the treatment of uterine fibroids. The size, shape, and configuration of such a combination imaging and therapy vaginal probe are believed to be specific to this particular access path through the vaginal canal, for rendering the HIFU therapy in treating obstetrical and gynecological medical conditions.

TABLE 2

Major axis length (cm) for a given a minor axis length that gives an ellipsoidal area equal to the area of a circular aperture of a specific diameter.				
Diameter Circular	Ellipsoid Minor Axis Length (cm)			
Aperture	4.5	5	5.5	6
4.5	4.5	4.1	3.7	3.4
5	5.6	5.0	4.5	4.2
5.5	6.7	6.1	5.5	5.0
6	8.0	7.2	6.5	6.0
6.5	9.4	8.5	7.7	7.0
7	10.9	9.8	8.9	8.2
7.5	12.5	11.3	10.2	9.4
8	14.2	12.8	11.6	10.7
8.5	16.1	14.5	13.1	12.0
9	18.0	16.2	14.7	13.5
9.5	20.1	18.1	16.4	15.0

[0094] FIG. 9 illustrates a first embodiment for mounting a HIFU module 123 onto a distal end of a prior art transvaginal imaging probe 120. Transvaginal imaging probe 120 includes an imaging transducer array 122. HIFU module 123 is sized and shaped to fit over the distal end of transvaginal imaging probe 120 and incorporates a cylindrical shaft 124 that has a cylindrical bore 126. Cylindrical bore 126 is sized to easily slide over the distal end of transvaginal imaging probe 120 and in its wall is disposed a plurality of fluid passages 130. Those of ordinary skill in the art will readily understand that ultrasonic waves do not readily pass through air gaps, and water or other fluid filled balloons are often used to conduct an ultrasonic wave between the ultrasonic transducer from which it is transmitted and a target of interest. Fluid passages 130 are used to circulate degassed water through a balloon 140 (FIG. 10) that surrounds HIFU module 123. It is important that the water be degassed, as bubbles within the water increase cavitation effects, which will attenuate the ultrasonic waves. The water circulating through the balloon provides cooling to the transducer elements to avoid an unwanted buildup of heat. It is currently common practice to use a condom for a balloon, although other inert and flexible elastomeric materials could be used.

[0095] In FIG. 10, vaginal probe 120 has been inserted into cylindrical bore 126 of cylinder 124, and the imaging transducer array 122 is disposed within a void 138. Shaft

124 also includes electrical leads 128, which connect the HIFU transducer to the power amplifier that drives the HIFU transducer. Located atop cylinder 124 is a HIFU transducer mounting base 136. It should be noted that HIFU transducer mounting base 136 is also hollow, such that the transvaginal imaging probe 130 may pass completely through the center of HIFU transducer mounting base 136 so that imaging transducer array 122 is disposed within void 138 (see FIG. 9B). This configuration enables imaging transducer array 122 to transmit an ultrasound imaging pulse to the target of interest.

[0096] As shown in FIG. 10, HIFU therapy transducer 132 is pivotally mounted to HIFU transducer mounting base 136 at a pivot joint 134. This pivotal mounting enables a clinician to selectively target a wider variety of treatment areas within the female reproductive system by rotating the HIFU transducer about pivot joint 134. It is envisioned that the disposition of the HIFU transducer on pivotal mounting 134 will be adjusted prior to inserting the combination transvaginal probe and HIFU module into the vaginal canal. The angle of the HIFU transducer should be adjusted based on the relative position of the target area and treatment site. Once in the vaginal canal, the combination transvaginal imaging probe and HIFU module can be moved to a position that enables an ultrasonic image of the target area to be observed on a display and then adjusted to focus the HIFU wave onto a desired treatment site within the target area.

[0097] It is envisioned that a mechanical linkage (not shown) connected to HIFU transducer 132 can be added to enable the HIFU transducer to be selectively rotated about pivot joint 134 while the combination transvaginal probe and HIFU module is in the vaginal canal. This capability would provide a clinician greater flexibility in focusing the HIFU transducer on a particular treatment site. However, it should be noted that a skilled clinician can initially select an angle for the HIFU transducer relative to the longitudinal axis of the transvaginal imaging probe, insert the combination vaginal probe and HIFU module into the vaginal canal, and then manipulate the combination imaging probe and HIFU module while in the vaginal canal to acquire the image of the target area and focus the HIFU beam on the desired treatment site.

[0098] FIG. 11 illustrates an ultrasonic image 142 superimposed on the combination transvaginal probe and HIFU transducer illustrated in FIG. 10 (but without balloon 140). In FIG. 11, the HIFU transducer 132 has been focused on a treatment site 144. The synchronization and pulsating elements described earlier have been used to shift a noise section 146 away from treatment site 144, such that the clinician is provided with a noise-free real-time image of treatment site 144.

[0099] FIG. 12 illustrates another embodiment of a combination imaging and therapy transducer based on a prior art transvaginal imaging probe. A therapy transducer module 150 has been mounted onto transvaginal imaging probe 120. The design of the module is constrained by the anatomy involved in the transvaginal application of HIFU to uterine fibroids, as discussed above. Module 150 is mounted at the tip of the vaginal probe, and contains an opening through which the scan head (imaging transducer) transmits an ultrasound wave to obtain an image of the uterus, the fibroid, and any other structure of interest. The opening allows about

one half of the scan head to transmit the imaging ultrasound wave. The other half is covered by the module assembly, and does not have a window for imaging, and therefore does not contribute to the image. In other words, half of the ultrasound image obtained by the vaginal probe in this configuration is masked by the assembly and is blank. The main housing of the module is made of biocompatible, medical grade plastic. A chamber **158** can be filled with a fluid, such as degassed water, for the purpose of coupling the HIFU to adjacent tissue. A water circulation system is used to circulate degassed cold water through chamber **158** for both cooling of the HIFU transducer and carrying away any cavitation bubbles that may be generated during the HIFU excitation. The water conduits extend through the plastic housing and two holes disposed on opposite sides of a central passage (not shown). Stainless steel needle stock can be employed for tubes **155** carrying the water in and out of the chamber. Tubes **155** run along the shaft of the vaginal probe adjacent to a coaxial cable **153** employed for energizing the HIFU transducer. A cover **159** attaches the membrane which forms chamber **158** to module **150**.

[0100] Further details of therapy transducer module **150** are provided in FIG. 13. A HIFU transducer **154** is disposed on a rim cut inside a brass bowl **152** that is affixed with an appropriate adhesive to module **150**. An electrical connection to the HIFU transducer is made through coaxial cable **153** that runs along the shaft of the probe. Preferably, the HIFU transducer is a concave, fixed focused transducer, operating at a center frequency of about 2.0 MHz. The radius of curvature of this embodiment of the HIFU transducer is about 55 mm, and its aperture diameter is about 35 mm. The focus of the HIFU transducer is within the imaging plane of the imaging probe (preferably an ATL, Inc., Model C9-5 transvaginal probe). In fact, the imaging plane intersects the HIFU beam envelope (cone shaped) through its center, placing both the focus and the HIFU beam longitudinal axis in the imaging plane, as can be seen in FIG. 14.

[0101] The HIFU transducer frequency was selected based on several requirements, including: (1) the ability to administer HIFU therapy to uterine fibroids up to a maximum distance of about 6 cm from the cervix; and, (2) an intensity gain of about 20 dB from the transducer surface to the focal spot, providing about 1,000 W/cm² at the focus, and about 50 W/cm² at the transducer surface. These are all reasonable values for both treatment and transducer operation. Two different embodiments of chambers containing degassed water are contemplated for the purpose of coupling the HIFU to adjacent tissue. These embodiments include a chamber containing just the HIFU transducer, and a chamber containing both the HIFU transducer and the imaging scan head.

[0102] FIG. 14 illustrates a combination transvaginal probe and HIFU transducer with both the imaging and HIFU transducer energized and chamber **158** filled with fluid. The HIFU transducer produces a cone-shaped HIFU wave **162** that is focused at a focal point **166**. The imaging transducer generates a scanning ultrasound wave **160**. It should be noted that HIFU wave **162** is within scanning wave **160**. Thus, focal point **166** can be readily seen in the image provided by scanning ultrasound wave **160**.

[0103] FIG. 15 illustrates an alternative design of a therapy transducer module **170** mounted on transvaginal

imaging probe **120**. As in the previous embodiment, imaging transducer array **122** is partially occluded by module **170**, and thus only a partial ultrasound image is generated. A HIFU therapy transducer **174** is mounted on a brass ring **178**, in a manner similar to the configuration in the previous embodiment. A fluid filled chamber **158a** encloses HIFU therapy transducer **174**. The most significant difference between the embodiment illustrated in FIG. 15 and the embodiments illustrated in FIGS. 13 and 14 is that fluid filled chamber **158a** of FIG. 15 only encloses HIFU therapy transducer **174**, and not imaging transducer array **122** as well.

[0104] FIGS. 16 and 17 illustrate an embodiment of probe usable in the present invention in which the HIFU therapy transducer and imaging transducer have been integrated into a single device. It is anticipated that as the combination of real-time imaging and HIFU therapy gains acceptance, clinicians will desire an integrated device rather than a HIFU transducer and a imaging transducer configured as two separate components, mounted together on a single probe. An integrated imaging transducer and a therapy transducer are formed as a combination transvaginal probe **180** as shown in these Figures. FIG. 17 illustrates that the angle of a paddle head **186** containing both the therapy and imaging transducers is movable relative to the body of combination transvaginal probe **180**. As was discussed in regard to the first embodiment of the transducer module that included the pivoting HIFU transducer, it is expected that paddle head **186** will be placed in a desired position prior to placing combination transvaginal probe **180** into a patient's vaginal canal. However, it is again envisioned that a linkage mechanism can be incorporated that will enable paddle head **186** to be moved relative to the handle portion of combination transvaginal probe **180**, while the paddle head is disposed in the vaginal canal. As noted earlier, the paddle head configuration is particularly well suited for use in the vaginal canal.

[0105] FIGS. 18 and 19 illustrates the paddle head probe with imaging transducers **182** and **182a** positioned at two different angles relative to the longitudinal axis of the paddle head. In FIG. 18, imaging transducer **182** is generally parallel to the axis, while in FIG. 19, an imaging transducer **182a** forms an angle of 90° relative to the axis. Those of ordinary skill in the art will recognize that the spatial orientation of the imaging transducer determines the plane of the scanning field. It should be noted that imaging transducers **182** and **182a** comprise a one-dimensional (1D) phased array of transducer elements, and a linear array concentric ring HIFU transducer **184** is provided. Those of ordinary skill in the art will readily understand that the 1D phased array imaging transducers allow the ultrasound waves that are generated thereby to be steered and focused through a substantial range in a plane, while the concentric phased array of the HIFU transducer can only be electronically focused at different points along its central axis. The probe can thus remain stationary while the scanning ultrasonic wave are steered and/or focused at a target area and the HIFU waves are focused on a treatment site within the target area.

[0106] Also shown in FIG. 19 is a vibrating element **190**. When activated, vibrating element **190** causes the focal point of the therapeutic ultrasonic wave to be varied, thus enlarging the size of the treated area within a limited portion

of the target area without requiring the clinician to move the probe. Preferably, the clinician can select from two vibrational patterns; a first pattern that involves a vibrational frequency in the range of 1 to 5 Hz (thereby avoiding the heating of tissue not associated with the treatment site), and a second pattern that involves a vibrational frequency in the range of 10 to 50 Hz (thereby increasing an amount of energy applied to the treatment site, while avoiding undesired cavitation effects). While a specific type of vibrating element is not required, it is envisioned that readily available electromechanical vibrating elements will be employed for this purpose. It should be noted that vibrating element 190 could be beneficially incorporated into other probe embodiments as well, and is not limited to only the embodiment illustrated in FIG. 19.

[0107] FIG. 20 illustrates a paddle head 186' of a combination transvaginal probe 180' that includes imaging transducer 182 and a HIFU transducer 184a. Both imaging transducer 182 and HIFU transducer 184a comprise 1D phased array elements oriented so that the respective imaging and therapeutic ultrasound signals can be steered and focused in substantially the same plane, i.e., in a plane aligned with a longitudinal axis of the combination transvaginal probe. The 1D phased array elements of HIFU transducer 184a are generally semi-circular in shape, due to its slightly concave configuration.

[0108] In FIG. 21, a paddle head 192 of a combination transvaginal probe 194 is illustrated. Paddle head 192 includes a two-dimensional (2D) phased array imaging transducer 196 and a 2D phased array HIFU transducer 198. The 2D phased array elements of both the imaging transducer and HIFU transducer can thus be electronically steered and focused within a substantial conical volume, providing the clinician the capability to electronically control the location of the target area that is imaged and the location of the treatment site to which the HIFU waves are administered.

[0109] Mice Study

[0110] A laboratory study has shown that uterine fibroid tumors in a mouse can be treated completely, achieving nearly 100% shrinkage, using HIFU therapy. An Abstract of a paper submitted to the American Journal of Obstetrics and Gynecology to describe this study is included below, with minor modifications.

[0111] The objective of the study was to investigate the potential efficacy of high intensity focused ultrasound (HIFU) for the treatment of uterine fibroid tumors. A total of 60 female athymic nude mice were inoculated subcutaneously with 3.5×10^6 ELT-3 cells, a uterine fibroid tumor cell line. Tumor development was monitored using subcutaneous caliper measurements of the tumors. The HIFU probe was a concave, single-element high-power transducer, operating at a frequency of 3.5 MHz, and an intensity of 2000 WM/cm². The HIFU treatment consisted of scanning the tumors for 30-60 seconds, based on the tumor size. A single HIFU-treatment resulted in a tumor reduction of 91% within one month of the treatment. Histological analysis of HIFU-treated tumors showed coagulation necrosis, and nuclear fragmentation of tumor cells. It is thus concluded that the HIFU effectively reduced uterine fibroid tumor size in a nude mouse model. Further studies are needed to assess the in-situ response of uterine fibroids to HIFU treatment.

[0112] This study presents an important result; uterine fibroids can be treated at least twice to achieve a desired tumor shrinkage percentage. Several treatments could provide an optimal outcome for the patient. Such method may be valuable for large tumors that may not shrink to a desired volume, with a single treatment.

[0113] EKER Rat Study

[0114] Another study has shown that HIFU therapy can cause shrinkage of uterine fibroid tumors in a rat model (EKER rats). This study was conducted on an in-situ model of the uterine fibroid. Sham-treated animals did not show any tumor shrinkage. Instead, their tumors grew to about 85 times the volume at the time of treatment. In contrast, HIFU-treated animals showed tumor shrinkage of about 80% (20% of the volume at the time of treatment, after 3 months). Of particular interest in the results obtained in this study is the response of individual animals to the treatment. When tumors were completely treated, shrinkage was not optimal, perhaps due to fibrosis of the necrotic tumor instead of the absorption by the body. It should be noted that a histological analysis has not been performed yet to provide a definitive conclusion. When tumors were incompletely treated, especially when areas of viable tumor existed around the HIFU lesion, shrinkage was optimal, with minimal fibrosis.

[0115] This study presents an important result; an effective tumor de-bulking with significant shrinkage may be provided by HIFU-treatment procedures that create scattered lesions in the tumor, to allow body's macrophage absorption of the necrosis area, without fibrosis. This procedure may be combined with the above procedure of multiple treatments to achieve complete shrinkage and/or optimal de-bulking to a desired volume.

[0116] Cytokine Study

[0117] Also investigated was the inflammatory response of the body to HIFU treatment, and its possible effect on tumor necrosis. A host of cytokines (non-antibody proteins, released by macrophages (actively phagocytic cells), on contact with a specific antigen and which act as intercellular mediators, as in the generation of immune response) are known to be involved in such inflammatory response. It has been shown that therapeutic ultrasound has a stimulatory effect on the production of cytokines. The cytokine production is a signaling mechanism that results in attraction of more macrophages, and an enhanced immune response.

[0118] This study presents an important implication. The inflammatory response of the body to HIFU treatment may provide an enhanced rate of tumor shrinkage due to enhanced cytokine production. This mechanism may provide grounds for a treatment procedure that involves the production of scattered HIFU lesions in the uterine fibroid tumor, and obtaining an optimal tumor shrinkage due to enhanced immune response.

[0119] Synergistic Treatment

[0120] Synergistic effects of therapeutic ultrasound and anti-tumor compounds may provide a mechanism for treatment for uterine fibroids, involving a combination therapy using both anti-tumor drugs and HIFU. This management has two possibilities, including the use HIFU with the drugs currently available for uterine fibroids (GnRH agonists).

These drugs can shrink the fibroids temporarily. As soon they are discontinued, the fibroids grow back to their original size. Since these drugs have side effects, they are primarily used for shrinking the fibroids before a myomectomy (surgical removal of the fibroids). HIFU treatment may be performed at the time when maximal shrinkage of the tumors due to drugs has occurred, thereby fixing the tumor size and preventing tumor re-growth. The second possibility is to use HIFU with the new anti-tumor compounds which may offer further advantages.

[0121] Methods of Administering the HIFU Therapy

[0122] Several methods for administering HIFU therapy of uterine fibroids are envisioned. These include the treatment of the entire tumor in a single procedure. It has been observed that a complete tumor treatment (100% shrinkage) may be obtained using this method. Alternatively, the tumor may be treated in several sessions, with sufficient time between each session for the macrophages in the patient's body to clear away the necrotic tissue resulting from the previous treatment session, effectively debriding the treatment site and exposing remaining tumor tissue for the next HIFU therapy session. In each session, a remaining part of the tumor is treated. A complete tumor treatment (100% shrinkage) in all of the tumors treated using this method has been observed. Scattered HIFU lesions in a tumor may also provide an optimal shrinkage, with minimal fibrosis. Several HIFU therapy sessions may be needed to completely eradicate the tumor. Further, as noted above, the treatment of a tumor using a combination of HIFU and drugs may yield synergistic results, particularly by beginning the HIFU therapy when the maximum benefit of the drug therapy on the tumor has been realized.

[0123] Although the present invention has been described in connection with the preferred form of practicing it and modifications thereto, those of ordinary skill in the art will understand that many additional modifications can be made thereto within the scope of the claims that follow. Accordingly, it is not intended that the scope of the invention in any way be limited by the above description, but instead be determined entirely by reference to the claims that follow.

The invention in which an exclusive right is claimed is defined by the following:

1. A method for using ultrasound to simultaneously image a target area and to provide therapy to a treatment site disposed within said target area, producing a lesion in a blood vessel that occludes a blood supply relative to a region, comprising the steps of:

(a) providing:

- (i) a scanning ultrasonic transducer system adapted to scan a target area and to provide imaging data for said target area;
- (ii) a processor adapted to process said imaging data;
- (iii) a display capable of providing a visual representation of said imaging data to a user; and
- (iv) a therapeutic ultrasonic transducer system adapted to provide waves of high intensity focused ultrasound (HIFU) to said treatment site;

- (b) energizing said scanning ultrasonic transducer system to continually scan said target area to produce said imaging data;
- (c) displaying a visual representation of said imaging data to the user on the display to produce a displayed target area;
- (d) selecting the treatment site from within the displayed target area proximate a blood vessel supplying blood to the region; and
- (e) directing the therapeutic waves of the HIFU at the treatment site with the therapeutic ultrasonic transducer system, said therapeutic ultrasonic transducer system being synchronized relative to the scanning ultrasonic transducer system such that any noise in said imaging data arising from said therapeutic waves is shifted away from the treatment site in the displayed target area, enabling the treatment site to be observed in real time as the therapeutic waves of the HIFU are administered to the treatment site, said therapeutic waves being of sufficient intensity to form a lesion in the blood vessel that occludes the blood vessel, preventing blood from continuing to flow into the region, so that oxygen and nutrients conveyed by blood flowing through the blood vessel do not reach the region.

2. The method of claim 1, further comprising the steps of:

- (a) initially energizing the therapeutic ultrasonic transducer system at a reduced energy level so as to produce a pulsed wave that is not energetic enough to produce a therapeutic effect at the treatment site, but is sufficiently energetic to produce a change in an echogenicity of tissue at the treatment site, a focal point of the therapeutic ultrasonic transducer system being visually apparent in the displayed target area visually represented on the display where the echogenicity of the tissue has thus been changed;
- (b) moving the focal point of the therapeutic ultrasonic transducer system to a desired position; and
- (c) increasing the energy level of the therapeutic ultrasonic transducer system to a therapeutic level to generate the therapeutic waves with sufficient energy to produce a desired therapeutic effect at the focal point.

3. The method of claim 2, further comprising the step of:

- (a) storing the visual representation of the focal point in the displayed target area for the position at which the therapeutic waves of the HIFU are being administered;
- (b) reducing the energy level of the therapeutic ultrasonic transducer system to the reduced level of the pulsed wave after the desired therapeutic effect has been achieved at the focal point;
- (c) moving the focal point of the therapeutic ultrasonic transducer system to a different desired position to define a new treatment site, said focal point being visually apparent in the displayed target area due the change in the echogenicity caused by the reduced level of the pulsed wave at the new treatment site in relationship to the visual representation of the focal point stored in step (a) of this claim;
- (d) energizing said therapeutic ultrasonic transducer system; thereby producing the therapeutic waves of HIFU directed at the new treatment site; and

- (e) repeating steps (a)-(d) of this claim until the therapeutic waves of HIFU have been administered to all desired treatment sites, the visual representation of all focal points on the display at which the therapeutic waves of the HIFU were previously administered enabling positions of each new treatment sites to be readily selected in relationship to previous treatment sites.
4. The method of claim 1, further comprising the steps of:
- (a) monitoring the displayed target area on the display for any changes in an area outside the treatment site caused by the therapeutic waves of HIFU delivered to the treatment site; and
- (b) de-energizing the therapeutic ultrasonic transducer system to prevent further changes to the area outside the treatment site, even if the desired therapeutic effect has not yet been achieved at the treatment site.
5. The method of claim 1, further comprising the step of processing the imaging data to effect at least one of: a scan conversion processing, a color flow processing, a Doppler processing, a B-mode processing, and an M-mode processing.
6. The method of claim 1, wherein the target area is associated with a reproductive system of a mammalian female.
7. The method of claim 6, wherein the therapeutic waves of the HIFU are administered to produce a lesion in the blood vessel to therapeutically affect a region that includes one of: a uterine fibroid, an endometrial polyp, a follicular cyst, a polycystic ovary, a dermoid cyst, a corpus luteum cyst, an ectopic pregnancy, a cornual pregnancy, a multifetal pregnancy, a uterine malformation, an endometrial hyperplasia, an adenomyosis condition, an endometriosis condition, an excessive bleeding condition, a placental abruption, a fetal anomaly, and a twin-twin infusion.
8. The method of claim 1, further comprising the step of:
- (a) providing a probe incorporating both the scanning ultrasonic transducer system and the therapeutic ultrasonic transducer system and having a size and shape adapted to be inserted through one of:
- a human vaginal canal;
 - a human rectum;
 - a human abdominal cavity; and
 - a laparoscopic dermal incision;
- (b) inserting the probe through a part of the human body through which it is adapted to be inserted; and
- (c) advancing the probe until it is adjacent to the target area before energizing the therapeutic ultrasonic transducer system.
9. The method of claim 1, wherein said therapeutic ultrasonic transducer system generates the therapeutic waves of the HIFU at frequencies within the range of 0.5 MHz to 10 MHz.
10. The method of claim 2, further providing a blood soluble material that has a high vapor pressure, and further comprising the step of administering the blood soluble material to the selected blood vessel before initially energizing the therapeutic ultrasonic transducer system at a reduced energy level, such that bubbles produced by the interaction of the blood soluble material and the therapeutic wave at a focal point of the therapeutic wave are detected by the scanning ultrasonic transducer system..
11. The method of claim 1, wherein the therapeutic ultrasonic transducer system comprises a phased array of ultrasonic transducers, said step of directing the therapeutic waves comprising the step of varying a position of a focal point of the phased array.
12. The method of claim 11, wherein the phased array of ultrasonic transducers comprises a plurality of concentric transducer elements.
13. The method of claim 1, wherein the therapeutic ultrasonic transducer system includes a vibrating element, further comprising the step of energizing the vibrating element to vary a focal point of the therapeutic ultrasonic transducer system.
14. The method of claim 13, wherein the step of energizing the vibrating element comprises the step of causing the therapeutic ultrasonic transducer system to vibrate with a frequency in the range of 1 to 5 Hz so that the position of the focal point within the target area is varied.
15. The method of claim 13, wherein the step of energizing the vibrating element comprises causing the therapeutic ultrasonic transducer system to vibrate with a frequency in the range of 10 to 50 Hz, thereby increasing an amount of energy applied to the treatment site while avoiding undesired cavitation effects.
16. The method of claim 1, further comprising the step of causing a focal point of the therapeutic ultrasonic transducer system to be varied within the target area in a random manner.
17. The method of claim 1, wherein administering the therapeutic waves to produce the lesion cause at least one of: arresting a bleeding at the treatment site, preventing bleeding at the treatment site, and causing tissue necrosis at the treatment site.
18. The method of claim 17, wherein the necrosis of tissue at the treatment site is caused by cavitation effects.
19. The method of claim 1, wherein a desired therapeutic effect of administering the therapeutic waves is one of an ablation of tissue at the treatment site and a hemostasis at the treatment site.
20. A method for using ultrasound to visualize and to provide therapy to a treatment site within a target area, such that an image is displayed to a clinician in real time, to continually provide feedback to the clinician relating to a focal point of therapeutic waves of high intensity focused ultrasound (HIFU) and a change in the treatment site, said method enabling a plurality of lesions to be produced in blood vessels supplying a region to occlude blood flow through the blood vessels into the region, comprising the steps of:
- (a) providing:
- a scanning ultrasonic transducer system adapted to scan the target area with a probe and to provide imaging data for said target area;
 - a processor adapted to process said imaging data;
 - a display that provides a visual representation of said imaging data to a clinician; and
 - a therapeutic ultrasonic transducer system adapted to provide the pulsed waves of the HIFU from the probe;

- (b) positioning the probe of the scanning ultrasonic transducer system and energizing the scanning ultrasonic transducer system so that an image comprising a visual representation of the target area is continually generated on the display as a displayed target area;
 - (c) directing the therapeutic ultrasonic transducer system at a prospective treatment site that is within the displayed target area;
 - (d) initially energizing the therapeutic ultrasonic transducer system at a reduced energy level that is so as to produce a pulsed wave that is not energetic enough to produce a therapeutic effect at the treatment site, but is sufficiently energetic to produce a change in an echogenicity of tissue at the treatment site, a focal point of the therapeutic ultrasonic transducer system being visually apparent in the displayed target area visually represented on the display where the echogenicity of the tissue has thus been changed;
 - (e) moving the focal point of the therapeutic ultrasonic transducer system to a desired position on a blood vessel;
 - (f) increasing the energy level of the therapeutic ultrasonic transducer system to a therapeutic level to produce the therapeutic waves with sufficient energy to produce a lesion in the blood vessel at the focal point; and
 - (g) repeating steps (c) through (f) for treatment sites comprising each additional blood vessel from the plurality of blood vessels, until blood flow into the region is substantially terminated.
- 21.** The method of claim 20, further comprising the step of:
- (a) storing the visual representation of the focal point in the displayed target area for the position at which the therapeutic waves of the HIFU are being administered;
 - (b) reducing the energy level of the therapeutic ultrasonic transducer system to the reduced level of the pulsed wave after the desired therapeutic effect has been achieved at the focal point;
 - (c) moving the focal point of the therapeutic ultrasonic transducer system to a different desired position within the displayed target area to define a new treatment site, said focal point being visually apparent in the displayed target area due to the change in the echogenicity caused by the reduced level of the pulsed wave at the new treatment site in relationship to the visual representation of the focal point stored in step (a) of this claim;
 - (d) energizing said therapeutic ultrasonic transducer system; thereby producing the therapeutic waves of HIFU directed at the new treatment site; and
 - (e) repeating steps (a)-(d) of this claim until the therapeutic waves of HIFU have been administered to all desired treatment sites, the visual representation of all focal points on the display at which the therapeutic waves of the HIFU were previously administered enabling positions of each new treatment sites to be readily selected in relationship to previous treatment sites.
- 22.** The method of claim 20, further comprising the step of monitoring the displayed target area to determine with the desired effect has been obtained at a current treatment site before administering the therapeutic waves of the HIFU to a new treatment site.
- 23.** The method of claim 20, further comprising the step of processing the imaging data to effect at least one of: a scan conversion processing, a color flow processing, a Doppler processing, a B-mode processing, and an M-mode processing.
- 24.** The method of claim 20, wherein the target area is the reproductive system of a mammalian female, and the therapeutic waves of the HIFU are administered to the region to treat at least one of: a uterine fibroid, an endometrial polyp, a follicular cyst, a polycystic ovary, a dermoid cyst, a corpus luteum cyst, an ectopic pregnancy, a cornual pregnancy, a multifetal pregnancy, a uterine AV malformation, an endometrial hyperplasia, an adenomyosis condition, an endometriosis condition, and an excessive bleeding condition.
- 25.** The method of claim 20, wherein the probe has a size and shape adapted to be inserted through one of: a vaginal canal, a rectum, an abdominal cavity, and a laparoscopic incision, further comprising the steps of:
- (a) inserting the probe into an area of the body through which the probe is adapted to be inserted; and
 - (b) advancing the probe until the probe is adjacent to the target area.
- 26.** The method of claim 20, wherein said therapeutic ultrasonic transducer system generates the therapeutic waves of the HIFU at frequencies within the range of 0.5 MHz to 10 MHz.
- 27.** The method of claim 26, wherein said therapeutic ultrasonic transducer system generates the therapeutic waves of the HIFU at frequencies within the range of 3.4 MHz to 3.6 MHz.
- 28.** The method of claim 20, wherein the therapeutic ultrasonic transducer system comprises a phased array of transducer elements that enable focusing of the therapeutic waves of the HIFU.
- 29.** The method of claim 28, wherein the phased array of transducer elements are arranged in a concentric pattern.
- 30.** The method of claim 20, wherein the therapeutic ultrasonic transducer system includes a vibrating element, further comprising the step of energizing the vibrating element to vibrate the therapeutic ultrasonic transducer system, so that a focal point of the therapeutic ultrasonic transducer system is varied.
- 31.** The method of claim 30, wherein the step of energizing the vibrating element comprises causing the therapeutic ultrasonic transducer system to vibrate at a frequency in the range of from 1 to 50 Hz.
- 32.** The method of claim 20, wherein the desired effect produced by causing lesions that occlude the plurality of blood vessels comprises one of a cauterization of tissue, a necrosis of tissue, and an ablation of tissue at the treatment site.
- 33.** A method for treating a tumorous growth by damaging selected regions within the tumorous growth, comprising the steps of:

(a) providing:

- (i) a scanning ultrasonic transducer system adapted to scan a target area and to produce imaging data for said target area;
- (ii) a processor adapted to process said imaging data;
- (iii) a display that is adapted to present a visual representation of said imaging data; and
- (iv) a high intensity ultrasonic transducer system that is adapted to produce high intensity focused ultrasound (HIFU) capable of damaging tissue within the tumorous growth;

(b) positioning and energizing the scanning ultrasonic transducer system to continually produce an image of the target area on the display comprising a displayed target area;

(c) selecting a treatment site within the tumorous growth that is visually represented in the displayed target area;

(d) focusing pulsed HIFU produced by the high intensity ultrasonic transducer system on the treatment site that was selected to damage tissue within the tumorous growth;

(e) focusing the high intensity ultrasonic transducer system onto a different selected region within the tumorous growth; and

(f) repeating steps (d) through (e) until a desired pattern of damaged areas in the tumorous growth has been achieved.

34. The method of claim 33, further comprising the step of monitoring a condition of each treatment site in the tumorous growth to determine when sufficient tissue has been damaged before moving to a new treatment site.

35. The method of claim 33, further comprising the step of repeating steps (a) to (f) at spaced-apart intervals of time, to enable any tissue in the tumorous growth that was destroyed by the HIFU to be removed by natural bodily processes, until the tumorous growth has been substantially eliminated.

36. The method of claim 33, further comprising the steps of:

- (a) initially energizing the high intensity ultrasonic transducer system at a reduced energy level so as to produce a pulsed wave that is not energetic enough to damage the tissue at the treatment site, but is sufficiently energetic to produce a change in an echogenicity of the tissue at the treatment site, a focal point of the high intensity ultrasonic transducer system being visually apparent in the displayed target area visually represented on the display where the echogenicity of the tissue has thus been changed;
- (b) moving the focal point of the high intensity ultrasonic transducer system within the displayed target area to a desired position; and
- (c) increasing the energy level of the high intensity ultrasonic transducer system to a therapeutic level to produce therapeutic waves with sufficient energy to damage the tissue of the tumorous growth at the focal point.

37. The method of claim 33, further comprising the step of de-energizing the high intensity ultrasonic transducer if the displayed target area shows that an undesired change has taken place to tissue in the target area, even if a desired level of damage to tissue within the tumorous growth has not yet been achieved.

38. The method of claim 33, further comprising the step of processing the imaging data comprises to effect at least one of: a color flow processing, a Doppler processing, a B-mode processing, and an M-mode processing.

39. The method of claim 33, wherein the target area includes the reproductive system of a mammalian female, and wherein the tumorous growth is one of a uterine fibroid, an endometrial polyp, a follicular cyst, a polycystic ovary, a dermoid cyst, and a corpus luteum cyst.

40. The method of claim 33, further comprising the step of providing a probe incorporating both the scanning ultrasonic transducer system and the high intensity ultrasonic transducer system having a size and shape adapted to be inserted through one of a vaginal canal, a rectum, an abdominal cavity, and a laparoscopic incision.

41. The method of claim 33, wherein said high intensity ultrasonic transducer system generates the therapeutic waves of the HIFU at frequencies within the range of 0.5 MHz to 10 MHz.

42. The method of claim 36, further providing a blood soluble material that has a high vapor pressure, and further comprising the step of administering the blood soluble material to the treatment site before initially energizing the therapeutic ultrasonic transducer system at a reduced energy level, such that bubbles produced by the interaction of the blood soluble material and the therapeutic wave at a focal point of the therapeutic wave are detected by the scanning ultrasonic transducer system.

43. The method of claim 33, wherein the damage to tissue within the tumorous growth is achieved by causing one of: cauterization of the tissue, necrosis of the tissue, and ablation of the tissue.

44. The method of claim 35, wherein macrophages remove the tissue that was destroyed from the tumorous growth.

45. A system for simultaneously using ultrasound for both imaging and therapeutic purposes, enabling a lesion to be produced in a blood vessel to occlude blood flow, comprising:

- (a) an ultrasonic scanning transducer disposed on a probe, said ultrasonic scanning transducer being adapted to generate an ultrasonic scanning wave and to receive the ultrasonic scanning wave after it is reflected from a target area in a patient's body, producing a signal that is useful for deriving imaging data for the target area;
- (b) a processor electrically coupled to the scanning ultrasonic transducer system capable to receive the signal, said processor processing the signal to produce the imaging data;
- (c) a display electrically coupled to the processor, said display presenting a visual representation of the imaging data;
- (d) a therapeutic ultrasonic transducer disposed on the probe and adapted to generate a pulsed high intensity focused ultrasonic (HIFU) therapeutic wave directed at a treatment site within the target area;

- (e) a control circuit electrically coupled to the therapeutic ultrasonic transducer system that synchronizes generation of the pulsed HIFU therapeutic wave relative to the ultrasonic scanning wave produced by the scanning ultrasonic transducer system, such that any noise within the imaging data arising from the pulsed HIFU therapeutic wave is shifted within the visual representation of the imaging data appear outside the treatment site, said control circuit providing sufficient energy to the therapeutic ultrasound transducer to cause a lesion in a blood vessel that is included in the visual representation of the target area, so that blood flow through the blood vessel to a region is occluded by the lesion; and
- (f) a power supply electrically coupled to supply an electrical current to energize the scanning ultrasonic transducer system, the therapeutic ultrasonic transducer system and the control circuit.
46. The system of claim 45, wherein the processor processes the signal to effect at least one of: a color flow processing, a Doppler processing, a B-mode processing, and an M-mode processing, said processor storing a portion of the imaging data that defines each position at which the pulsed HIFU therapeutic wave was focused on the treatment site.
47. The system of claim 45, wherein the target area is the reproductive system of a mammalian female.
48. The system of claim 47, wherein the pulsed HIFU therapeutic wave is employed to treat one of: a uterine fibroid, an endometrial polyp, a follicular cyst, a polycystic ovary, a dermoid cyst, a corpus luteum cyst, an ectopic pregnancy, a cornual pregnancy, a multifetal pregnancy, a uterine malformation, an endometrial hyperplasia, an adenomyosis condition, an endometriosis condition, and an excessive bleeding condition.
49. The system of claim 45, wherein the probe has a size and shape adapting it to being inserted into and manipulated within a human vaginal canal.
50. The system of claim 49, wherein the probe comprises a handle having the ultrasonic scanning transducer and the therapeutic ultrasonic transducer mounted on a distal end of the handle.
51. The system of claim 50, wherein the therapeutic transducer is mounted to the handle with a pivot joint, enabling a disposition of the transducer relative to the handle to be adjusted by manipulating the therapeutic transducer about the pivot joint.
52. The system, of claim 50, wherein the therapeutic transducer includes a fluid filled cavity that couples ultrasonic wave emitted by the therapeutic transducer to the treatment site.
53. The system of claim 45, wherein probe has a size and shape adapting it to being inserted into and manipulated within a human rectum.
54. The system of claim 45, wherein the therapeutic ultrasonic transducer generates frequencies within the range of 0.5 MHz to 10 MHz.
55. The system of claim 45, wherein the therapeutic ultrasonic transducer generates frequencies within the range of 3.4 MHz to 3.6 MHz.
56. The system of claim 45, wherein the therapeutic ultrasonic transducer comprises a phased array of transducer elements that enables a focal point of the therapeutic ultrasonic transducer to be selectively varied.
57. The system of claim 56, wherein the phased array of transducer elements is configured in a concentric pattern.
58. The system of claim 45, wherein the therapeutic ultrasonic transducer system comprises a vibrating element that when energized causes a focal point of the therapeutic ultrasonic transducer system to be randomly varied within the target area.
59. The system of claim 58, wherein the vibrating element vibrates with a frequency in the range of 1 to 5 Hz, variation of the focal point preventing undesired heating of tissue not associated with the treatment site.
60. The system of claim 58, wherein the vibrating element vibrates with a frequency in the range of 10 to 50 Hz and increases an amount of energy applied to the treatment site while avoiding undesired cavitation effects.
61. A probe for administering ultrasound therapy from within a vaginal canal of a patient, said therapy being administered to a treatment site within the patient's body and outside the vaginal canal, comprising:
- (a) an elongate supporting structure having a distal end and a proximal end, said elongate supporting structure including a section at its proximal end that is adapted to be grasped and manipulated by a clinician to at least initially position the elongate supporting structure at a desired location within the vaginal canal of the patient;
 - (b) an imaging transducer disposed at the distal end of the elongate supporting structure, said imaging transducer being adapted to emit ultrasound imaging pulses when excited by an imaging signal for use in producing an image of a target area in the patient's body;
 - (c) a high intensity focused ultrasound (HIFU) transducer disposed at the distal end of the elongate supporting structure, proximate to the imaging transducer and sized and shaped to fit within the vaginal canal, said HIFU transducer having an aperture through which HIFU waves are transmitted, said aperture being of a sufficient size to produce therapeutic HIFU waves, so that the therapeutic HIFU waves have sufficient intensity remaining upon reaching the treatment site after being attenuated by their passage through up to 6 cm of intervening tissue, to achieve a desired therapeutic effect, while said therapeutic HIFU waves do not have so much intensity when emitted by the HIFU transducer as to damage adjacent tissue through which the therapeutic HIFU waves initially propagate toward the treatment site; and
 - (d) means for directing the therapeutic HIFU waves at the treatment site within the target area, said HIFU transducer being energized to render the HIFU therapy while the imaging transducer is energized to provide a signal for imaging the target area.
62. The probe of claim 61, wherein a maximum circumference of the aperture of the HIFU transducer, measured in a plane that is generally transverse to a longitudinal axis of the elongate supporting structure, is about 10.6 cm.
63. The probe of claim 61, wherein the desired therapeutic effect produced at the treatment site by the therapeutic HIFU waves comprises at least one of the following:
- (a) damage to undesired tissue;
 - (b) hemostasis of a blood vessel;
 - (c) necrosis of undesired tissue;
 - (d) ablation of undesired tissue; and
 - (e) obstruction of a blood vessel.

摘要(译)

用于在探针上同时使用超声以用于成像和治疗目的的方法和设备。探头通过使高强度聚焦超声(HIFU)波与成像换能器同步来限制不期望的干扰噪声对显示器的影响,以使噪声显示在图像的不与治疗部位重叠的区域中。在一个实施例中,HIFU首先以不会引起组织损伤的低功率水平通电,从而可以通过由HIFU引起的组织的回声性的变化来识别HIFU的焦点。一旦焦点适当地靶向期望的治疗部位,功率水平就增加到治疗水平。每个治疗部位的位置被存储并显示给用户,以实现多个间隔开的治疗部位。随着治疗的进行,治疗部位的任何变化都可以在实时,无噪声的图像中看到。HIFU波的优选应用是在血管中引起损伤,从而中断诸如肿瘤的区域的食物和氧的供应。因此肿瘤最终会被破坏。在优选的实施方案中,HIFU用于治疗女性生殖系统疾病,例如子宫肌瘤。可以间隔开的间隔重复HIFU治疗,直到任何剩余的纤维组织被破坏。
