(57) **ABSTRACT**

This invention provides hermetically-sealed handle assembly with a rotating trigger for use with disposable components, such as surgical clip appliers. The rotating trigger reduces the gripping force necessary to fully control the internal actuator mechanism to operate a disposable surgical clip applier to fully ligate a vessel or other tissue. The hermetic seal on the handle assembly prevents any patient fluids and other bioburden from entering the internal structures. This reduces the possibility of cross-contamination and the costs of sterilization.

FIG. 2

FIG. 3

FIG. 4

1

HERMETIC ROTATING HANDLE ASSEMBLY FOR A SURGICAL CLIP APPLIER FOR LAPAROSCOPIC PROCEDURES

CROSS REFERENCE TO RELATED APPLICATION

This application is a continuation of U.S. patent application Ser. No. 13/081,480, filed Apr. 6, 2011, now U.S. Pat. No. 8,715,299, entitled "Hermetic Rotating Handle Assembly For A Surgical Clip Applier For Laparoscopic Procedures," which claims priority to and the benefit of U.S. Provisional Application No. 61/321,237 filed Apr. 6, 2010, the contents of each of which are incorporated herein by reference.

FIELD OF THE INVENTION

This invention relates to a novel hermetic rotating handle assembly for a surgical clip applier for laparoscopic or endoscopic procedures.

BACKGROUND OF INVENTION

Laparoscopic and endoscopic surgical procedures are conducted through a small incision in the skin or natural body orifices. In order to operate, surgeons must use instruments that have a small enough cross section to fit within these small openings and long enough to reach the surgical area within the body.

Surgical instruments designed for these procedures are often separated into two components to reduce costs and minimize cross contamination.

The first component is a long and narrow disposable portion that is inserted into the small opening during surgery. These disposable components contain surgical tools, such as surgical jaws or surgical clip appliers, dissectors or other instruments, on the end which enters the patient. These disposable components also contain small actuators which control the operation of the surgical tools within the patient.

These small actuators on the first component are operatively attached to the second component of these surgical instruments. The second component is a non-disposable control unit for moving the long disposable component within the patient and operating the actuators to control the surgical tools on the disposable component. The second component is often a handle with a trigger. A surgeon may control the movement and placement of the disposable component by holding the handle and operate the small actuators by squeezing the trigger. For instance, a surgeon may squeeze the trigger to place a surgical clip over a vessel.

By separating these two components, the risk of cross contamination between separate patients or separate tissues on the same patient is reduced. The non-disposable control unit does not enter the patient and the contaminated long and narrow component is simply disposed after each surgical procedure is completed. In addition, costs are saved since medical providers only need to replace the disposable component between surgical procedures.

However, one the problems with currently existing surgical instruments used in these procedures is the possible contamination of the non-disposable control unit. This non-disposable component may still contact patient fluids during surgeries and become contaminated. This may be especially problematic for handle and trigger assemblies. In order for

2

a trigger to be squeezed and moveable, these assemblies have openings to their internal structures.

One solution to this problem is for medical providers to autoclave and sterilize each non-disposable component after each surgical procedure. However, the time needed to autoclave and sterilize these non-disposable handle and trigger assemblies is significantly high due to the need to sterilize the internal structures. This sterilization increases maintenance costs for medical providers. Current surgical clip appliers include many disposable handles since they cannot be sterilized effectively, even with hours in an autoclave.

According, the subject invention is a non-disposable hermetically-sealed handle assembly with a rotating trigger for use with disposable components, such as surgical clip appliers. The hermetic seal on the handle assembly prevents any patient fluids and other bioburden from entering the internal structures. This reduces the possibility of cross-contamination and the costs of sterilization.

SUMMARY OF THE INVENTION

There are additional features of the invention that will be described hereinafter and which will form the subject matter of the claims appended hereto. In this respect, before explaining at least one embodiment of the invention in detail, it is to be understood that the invention is not limited in its application to the details of construction and to the arrangements of the components set forth in the following description or illustrated in the drawings. The invention is capable of other embodiments and of being practiced and carried out in various ways. Also, it is to be understood that the phraseology and terminology employed herein are for the purpose of the description and should not be regarded as limiting.

The subject invention discloses an endoscopic surgical tool comprising, a housing comprising an upper portion and a handle; an actuating mechanism contained within the housing along a first axis, wherein the actuating mechanism is adapted to operatively couple to a disposable external shaft that extends away from the housing along a first shaft axis from a proximal end to a distal end, wherein the first axis and the first shaft axis are substantially parallel; a lever coupled at a proximal end to the actuating mechanism and extending in a downward direction, wherein the lever is pivotably coupled at a distal end to an internal shaft that extends along a second shaft axis that is substantially perpendicular to the first shaft axis; a first end of the internal shaft extending through a first opening in the housing proximate to the top of the handle, and further extending through a central opening of a first disc spring; a second end of the internal shaft extending through a second opening in the housing proximate to the top of the handle, and further extending through a central opening of a second disc spring, wherein the first opening and the second opening are substantially parallel with each other; a first trigger shaft comprising a first substantially semi-spherical top portion coupled to the first end of the internal shaft after extending through the first disc spring, wherein the first trigger shaft further comprises a first substantially half-cylindrical lower portion with a first substantially flat surface, wherein the first disc spring provides a first seal about the first end of the internal shaft by providing a first compressive force on the first substantially semi-spherical top portion of the first trigger shaft and an opposing second compressive force on the exterior surface about the first opening in the housing; a second trigger shaft comprising a second substantially semi-spherical top portion coupled to the second end of the

3

internal shaft after extending through the second disc spring, wherein the second trigger shaft further comprises a second substantially half-cylindrical lower portion with a second substantially flat surface, wherein the second disc spring provides a second seal about the second end of the internal shaft by providing a third compressive force on the second substantially semi-spherical top portion of the second trigger shaft and an opposing fourth compressive force on the exterior surface about the second opening in the housing, wherein the first and second substantially flat surface of the first and second trigger shafts couple to form a substantially cylindrical, lower trigger shaft defining a longitudinal axis; a hollow substantially cylindrical trigger grip coupled over the cylindrical lower trigger shaft; wherein application of compressive force to the trigger grip towards the handle rotates the cylindrical lower trigger shaft about the longitudinal axis in a first direction to rotate the first and second ends of the internal shaft in a direction away from the second shaft axis, wherein rotation of the internal shaft pivots the coupled lever to operate the actuating mechanism.

In another embodiment of the subject invention, the first and second trigger shafts comprise complementary configurations.

In another embodiment of the subject invention, the external shaft comprises a cartridge containing surgical clips.

In another embodiment of the subject invention, the distal end of the external shaft is adapted to receive an end effector.

In another embodiment of the subject invention, the end effector comprises a distally attached surgical jaws assembly.

In another embodiment of the subject invention, the first and second disc springs comprise conical spring washers.

In another embodiment of the subject invention, the housing is non-disposable.

In another embodiment of the subject invention, the cylindrical lower trigger shaft rotates about the longitudinal axis in a second direction, opposite the first direction, when the trigger is released.

In another embodiment of the subject invention, the housing comprises a single piece.

In another embodiment of the subject invention, the housing comprises two coupled pieces with complementary configurations.

The subject invention also discloses a hermetically sealed handle assembly for a surgical clip applier comprising: a housing comprising an upper portion and a lower handle; an actuating mechanism contained within the upper portion of the housing that controls a disposable cartridge containing surgical clips; a shaft extending from the housing containing rotating means so as to permit rotation of the shaft about an axis that extends substantially longitudinally through the shaft, wherein the shaft rotates in a first direction about an axis that extends substantially longitudinally through the shaft when a gripping force is applied to the shaft, and further wherein the actuating mechanism within the housing is coupled to the shaft such that rotation of the shaft operates the actuating mechanism.

There has thus been outlined, rather broadly, the more important features of the invention in order that the detailed description thereof that follows may be better understood, and in order that the present contribution to the art may be better appreciated. There are additional features of the invention that will be described hereinafter and which will form the subject matter of the claims appended hereto. These together with other objects of the invention, along with the various features of novelty, which characterize the inven-

4

tion, are pointed out with particularity in the claims annexed to and forming a part of this disclosure.

BRIEF DESCRIPTION OF THE DRAWINGS

Advantages of the present invention will be apparent from the following detailed description of embodiments thereof, which description should be considered in conjunction with the accompanying drawings, in which:

FIG. 1 illustrates an exploded view of a hermetically-sealed rotating trigger and handle assembly for a clip applier.

FIG. 2 illustrates a front view of the hermetically-sealed rotating trigger and handle assembly.

FIG. 3 illustrates a side cross-sectional view of the hermetically-sealed rotating trigger and handle assembly along line "A" of FIG. 2.

FIG. 4 illustrates a cross-sectional front internal view of the hermetically-sealed rotating trigger and handle assembly.

FIG. 5 illustrates a side view of the hermetically-sealed rotating trigger and handle assembly.

DETAILED DESCRIPTION OF THE EMBODIMENTS

While several variations of the present invention have been illustrated by way of example in particular embodiments, it is apparent that further embodiments could be developed within the spirit and scope of the present invention, or the inventive concept thereof. However, it is to be expressly understood that such modifications and adaptations are within the spirit and scope of the present invention, and are inclusive, but not limited to the following appended claims as set forth.

FIGS. 1-5 illustrate a hermetically-sealed handle and trigger assembly **101** with a handle **102** and a rotating trigger **103** for a surgical clip applier (not shown). FIG. 3 illustrates a side cross-sectional view of the handle and trigger assembly **101** as shown by lines "A" of FIG. 2. The hermetic seal on the handle and trigger assembly **101** prevents any patient fluids from entering the internal structures. This reduces the possibility of cross-contamination and the costs of sterilization, which allows the handle and trigger assembly **101** to be non-disposable.

The rotating trigger **103** rotates in a first direction that is substantially perpendicular to the length of the trigger **103** when squeezed in a direction towards handle **102**. The rotating trigger **103** rotates in a second direction, opposite the first direction, when released and moving away from handle **102**.

The elements of the handle and trigger assembly **101** include an external housing **107** that is formed by a hollow left half section **305** and a hollow right half section **306**. Hollow left half section **305** and hollow right half section **306** are complementarily shaped to each other. The housing **107** may be made of a polycarbonate, ABS, stainless steel or other suitable material known to those skilled in the art. The separate half sections **305** and **306** may be attached together by adhesives, fasteners, welding, or other attachment means known to those skilled in the art.

Left half section **305** has an upper left housing **305a**, a lower left half-handle housing **305b** and a hollow left hinge housing **305c**. Hollow left hinge housing **305c** has a traversing left opening **305d**.

Right half section **306** has an upper right housing **306a**, a lower right half-handle housing **306b**, and a hollow right

hinge housing 306c. Hollow right hinge housing 306c has a traversing right opening 306d.

An actuator mechanism 104 is contained within upper left housing 305a and upper right housing 306a. Once the left half section 305 and the right half section are connected to form the external housing 107, the upper left housing 305a and the upper right housing 306a form housing opening 106. This opening 106 contains the actuator mechanism 104 and allows it to control the disposable cartridge containing surgical clips and a plurality of distal end effectors. The internal actuator mechanism 104 of the subject invention may be any mechanism, known to those skilled in the art, which operates a cartridge containing surgical clips and a distal end effector that is controllable with pivotable lever 105.

A pivotable lever 105 has a top end 105a and a bottom end 105b. The top end 105a of lever 105 is operatively connected to actuator mechanism 104. Trigger shaft 310 is substantially perpendicular to lever 105. The top end 105a of lever 105 may pivot about the pivot point of bottom end 105b by rotating around the axis of trigger shaft 310.

Trigger shaft 310 has a left end 310a and a right end 310b. Trigger shaft bearings 309 are placed over left end 310a and right end 310b.

Left end 310a passes through left opening 305d of left hinge housing 305 and then passes through a spring seal washer 311. A left hinge element of the trigger 304 has an upper semi-spherical portion 304a with an indentation 304b that houses the spring seal washer 311. After passing through spring seal washer 311, left end 310a of trigger shaft 310 attaches within indentation 304b of the left hinge element of the trigger 304.

Right end 310b passes through left opening 306d of right hinge housing 306 and then passes through a spring seal washer 311. A right hinge element of the trigger 303 has an upper semi-spherical portion 303a with an indentation 303b. After passing through spring seal washer 311, right end 310b of trigger shaft 310 attaches within indentation 303b of the right hinge element of the trigger 303.

Right hinge element of the trigger 303 has a lower trigger spine 303c attached to upper semi-spherical portion 303a. Lower trigger spine 303c has a half-cylindrical shape with a substantially flat face 303d.

Left hinge element of the trigger 304 has a middle trigger spine 304c attached to upper semi-spherical portion 304a. The upper section of middle trigger spine 304c, proximate to semi-spherical portion 304a, has a half-cylindrical shape with a substantially flat face 304d. The lower section of middle trigger spine 304c, distal to semi-spherical portion 304a, has a substantially cylindrical shape. Left hinge element of the trigger 304 also has a lower substantially cylindrical trigger spine 304e attached to middle trigger spine 304c.

As left end 310a attaches within indentation 304b and right end 310b attaches within indentation 303b, substantially flat face 303d is attached to the opposing substantially flat face 304d above the lower section of middle trigger spine 304c. Once joined, flat faces 303d and 304d form a substantially cylindrical shape that is substantially equivalent in diameter to the lower section of middle trigger spine 304c. The right hinge element of the trigger 303 is torsionally fixed to the right end 310b of trigger shaft 310. The left hinge element of the trigger 304 is torsionally fixed to the left end 310a of trigger shaft 310.

A hollow substantially cylindrical trigger grip 301 has a top opening 301a and a bottom opening 301b. The trigger grip 301 is placed over the connected right hinge element

303 and left hinge element 304 through top opening 301a. The lower trigger spine 304e of left hinge element of the trigger 304 passes through bottom opening 301b, a bushing 307, a retaining ring 308 and is attached to an end cap 302.

FIG. 5 illustrates the rotating trigger in the resting position 103a and the squeezed position 103b. When a user applies gripping force to the trigger grip 301 by squeezing rotating trigger 103, the trigger grip 301, the lower trigger spine 303c, and the middle trigger spine 304c all begin to rotate about the axis of trigger shaft 310 in either a clockwise or counterclockwise direction. As trigger spine 304c begins to rotate, the left end 310a of trigger shaft 310 also begins to rotate in the same direction. Concurrently, as trigger spine 303c begins to rotate, the right end 310b of trigger shaft 310 also begins to rotate in the same direction. The rotation of trigger shaft 310 causes the top end 105a of lever 105 to begin to pivot about the pivot point of bottom end 105b by rotating around trigger shaft 310. The pivoting of top end 105a operates actuator mechanism 104 which controls the surgical clip applier distal end effector (not shown). Thus, application of gripping force to the trigger 103 operates the surgical clip applier.

Once a user releases the trigger grip 301, the trigger grip 301, the lower trigger spine 303c, and the middle trigger spine 304c all begin to rotate about the axis of trigger shaft 310 in the opposite clockwise or counterclockwise direction. The trigger shaft 310 rotating in an opposite direction causes the top end 105a of lever 105 to begin to pivot in an opposite direction about the pivot point of bottom end 105b by rotating around trigger shaft 310. The opposite pivoting of top end 105a releases the actuator mechanism 104 which controls the surgical clip applier distal end effector (not shown). Thus, release of gripping force to the trigger 103 stops the operation of the surgical clip applier.

The rotating trigger 103 reduces the gripping force necessary to fully pivot lever 105 to operate actuator mechanism 104 to operate a disposable surgical clip applier (not shown) to fully ligate a vessel or other tissue. In one embodiment of the subject application the gripping force required to fully actuate for full ligation is reduced from 25 lbs to 5 lbs.

The trigger assembly 101 and the rotating trigger 103 remain hermetically sealed in the resting 103a and squeezed 103b positions. A spring seal washer 311 around the left end 310a of trigger shaft 310 provides a compressive force against semi-spherical portion 304a and an opposing compressive force against housings 305a and 305c. Another spring seal washer 311 around the right end 310b of trigger shaft 310 provides a compressive force against semi-spherical portion 303a and an opposing compressive force against housings 306a and 306c. These opposing compressive forces on both sides and surrounding trigger shaft 310 provide an air seal between trigger 103 and housing 107. This air seal is maintained during rotation of trigger 103 from the resting 103a to squeezed position 103b.

Handle and trigger assembly 101 does not require a change of the trigger body volume inside the handle when the trigger 103 is gripped or released. This allows the handle and trigger assembly 101 to contain a completely air tight seal, making the assembly 101 infinitely reusable while reducing sterilization time. This also minimizes autoclave ineffectiveness and the possibility of cross contamination from patient to patient.

In embodiments of the subject invention, the washer seals 311, the bushing 307, the retaining ring 308 and the trigger shaft bearings 309 may be composed of titanium, plastic, steel or any combination thereof. In another embodiment of

the subject invention, the washer seals **311**, the bushing **307**, the retaining ring **308** and the trigger shaft bearings **309** may all be composed of a unitary construction.

What is claimed is:

1. An endoscopic surgical tool, comprising:

a housing comprising an upper portion and a handle, the handle having a top and a bottom, the top of the handle coupled to the upper portion of the housing;

an actuating mechanism disposed in the housing along a first axis, the actuating mechanism having a first shaft axis extending from a proximal end to a distal end, wherein the first axis and the first shaft axis are substantially parallel;

a lever coupled at a proximal end to the actuating mechanism and extending in a downward direction, wherein the lever is pivotably coupled at a distal end to a trigger shaft that extends along a second shaft axis that is substantially perpendicular to the first shaft axis;

a first end of the trigger shaft extending through a first opening in the housing proximate to the top of the handle, and further extending through a central opening of a first disc spring;

a second end of the trigger shaft extending through a second opening in the housing proximate to the top of the handle, and further extending through a central opening of a second disc spring, wherein the first opening and the second opening are substantially parallel with each other;

a first hinge element comprising a first substantially semi-spherical top portion coupled to the first end of the trigger shaft after extending through the first disc spring, wherein the first hinge element further comprises a first substantially half cylindrical lower portion with a first substantially flat surface, wherein the first disc spring provides a first seal about the first end of the trigger shaft by providing a first compressive force on the first substantially semi-spherical top portion of the first hinge element and an opposing second compressive force on the exterior surface about the first opening in the housing;

a second hinge element comprising a second substantially semi-spherical top portion coupled to the second end of the trigger shaft after extending through the second disc spring, wherein the second hinge element further comprises a second substantially half-cylindrical lower portion with a second substantially flat surface, wherein the second disc spring provides a second seal about the second end of the trigger shaft by providing a third compressive force on the second substantially semi-spherical top portion of the second hinge element and an opposing fourth compressive force on the exterior surface about the second opening in the housing, wherein the first and second substantially flat surface of the first and second hinge elements couple to form a substantially cylindrical trigger defining a longitudinal axis; and

a hollow substantially cylindrical trigger grip coupled over the cylindrical trigger;

wherein application of compressive force to the trigger grip towards the handle rotates the cylindrical trigger about the longitudinal axis in a first direction to rotate the first and second ends of the trigger shaft in a direction away from the second shaft axis, wherein rotation of the trigger shaft pivots the coupled lever to operate the actuating mechanism.

2. The endoscopic surgical tool of claim 1, wherein the first and second hinge elements comprise complementary configurations.

3. The endoscopic surgical tool of claim 1, wherein the first and second disc springs comprise conical spring washers.

4. The endoscopic surgical tool of claim 1, wherein the housing is nondisposable.

5. The endoscopic surgical tool of claim 1, wherein the cylindrical trigger rotates about the longitudinal axis in a second direction, opposite the first direction, when the cylindrical trigger is released.

6. The endoscopic surgical tool of claim 1, wherein the housing comprises a single piece.

7. The endoscopic surgical tool of claim 1, wherein the housing comprises two coupled pieces with complementary configurations.

8. An apparatus, comprising:

a housing including a proximal end portion and a distal end portion and defining an inner volume therebetween, the distal end portion of the housing including a distal opening configured to receive a removable cartridge;

an actuator mechanism disposed in the housing and configured to be operably coupled to the removable cartridge, the actuator mechanism including a trigger shaft defining a first axis about which the trigger shaft is configured to rotate; and

a trigger assembly operably coupled to the actuator mechanism, the trigger assembly configured to be moved between a first position relative to the housing and a second position relative to the housing to move the actuator mechanism between a first configuration and a second configuration,

the trigger assembly defining a central axis and including a trigger grip configured to rotate around the central axis of the trigger assembly as the trigger assembly is moved between the first position and the second position, the central axis being perpendicular to the first axis in at least one plane.

9. The apparatus of claim 8, wherein the housing includes a trigger assembly mounting portion having a first opening and a second opening, a first portion of the trigger shaft is disposed in the first opening of the trigger assembly mounting portion and a second portion of the trigger shaft is disposed in the second opening of the trigger assembly mounting portion such that the trigger shaft is rotatably coupled to the trigger assembly mounting portion.

10. The apparatus of claim 9, wherein the trigger assembly includes a first hinge element and a second hinge element, the first hinge element coupled to the first portion of the trigger shaft, and the second hinge element coupled to the second portion of the trigger shaft.

11. The apparatus of claim 9, further comprising:

a first sealing member disposed on the first portion of the trigger shaft; and

a second sealing member disposed on the second portion of the trigger shaft.

12. The apparatus of claim 11, wherein the first sealing member and the second sealing member are configured to prevent bioburden from entering the inner volume.

13. The apparatus of claim 8, wherein at least a portion of the actuator mechanism is disposed in the distal opening of the housing in the first configuration and the second configuration, the portion of the actuator mechanism disposed in the distal opening configured to prevent bioburden from entering the inner volume.

9

14. The apparatus of claim 8, further comprising:
a lever configured to operably couple the actuator mechanism to the trigger assembly.

15. The apparatus of claim 8, wherein the trigger assembly includes a trigger spine and the trigger grip is rotatably coupled to the trigger spine. 5

16. The apparatus of claim 8, wherein the removable cartridge includes a plurality of surgical clips, the actuator mechanism configured to operate the removable cartridge to ligate a vessel or tissue when the actuator mechanism moves between the first configuration and the second configuration. 10

17. An apparatus, comprising:

a housing including a proximal end portion and a distal end portion and defining an inner volume therebetween, the housing including a trigger assembly mounting portion having a first opening and a second opening; 15

an actuator mechanism disposed in the housing and configured to be operably coupled to a removable cartridge; and 20

a trigger assembly including a trigger shaft movably coupled to the housing, the trigger shaft including a first portion disposed in the first opening of the trigger shaft mounting portion and a second portion disposed in the second opening of the trigger assembly mounting portion, the trigger assembly including a first circular 25

10

sealing member disposed on the first portion of the trigger shaft and a second circular sealing member disposed on the second portion of the trigger shaft, the first circular sealing member and the second circular sealing member configured to prevent fluid from entering the inner volume,

the trigger assembly operably coupled to the actuator mechanism and configured to be moved between a first position relative to the housing and a second position relative to the housing to move the actuator mechanism between a first configuration and a second configuration. 30

18. The apparatus of claim 17, wherein the trigger assembly includes a trigger grip configured to rotate about an axis defined by the trigger assembly when the trigger assembly is moved between the first position and the second position. 35

19. The apparatus of claim 17, wherein the distal end portion of the housing includes a distal opening configured to receive the removable cartridge. 40

20. The apparatus of claim 17, wherein the removable cartridge includes a plurality of surgical clips, the actuator mechanism configured to operate the removable cartridge to ligate a vessel or tissue when the actuator mechanism moves between the first configuration and the second configuration. 45

摘要(译)

本发明提供了一种带有旋转触发器的气密密封手柄组件，用于一次性部件，例如手术施夹器。旋转触发器减小了完全控制内部致动器机构以操作一次性手术施夹器以完全结扎血管或其他组织所需的夹持力。手柄组件上的气密密封防止任何患者流体和其他生物负载进入内部结构。这降低了交叉污染的可能性和灭菌成本。
