The present application discloses several embodiments of a devices for maintaining visualization with a surgical scope. The embodiments of the device are adapted to shield, defog or clean the lens of the surgical scope while the surgical scope is being used to perform a surgical procedure within a patient's body. In one embodiment, a view optimizer is provided that is adapted to deliver at least one fluid to the objective lens of the laparoscope to clean and/or defog the objective lens of the laparoscope without the need to remove the laparoscope from the surgical field. In additional embodiments, a view optimizer is provided that is adapted to create leakage or venting of gas from the body cavity so as to ensure continuous gas flow from an insufflator.

## DEVICE FOR MAINTAINING VISUALIZATION WITH SURGICAL SCOPES

### TECHNICAL FIELD

**[0001]** The present application relates generally to various embodiments of a device for maintaining visualization with surgical scopes. More particularly, this application relates to various embodiments of a view optimizer adapted to shield, clean and de-fog the defog or clean lens of a surgical scope, such as a laparoscope, while the surgical scope is being used to perform a surgical procedure within a cavity of a patient's body.

### BACKGROUND OF THE INVENTION

**[0002]** Minimally invasive surgical procedures utilizing surgical scopes are desirable because they often provide one or more of the following advantages: reduced blood loss; reduced post-operative patient discomfort; shortened recovery and hospitalization time; smaller incisions; and reduced exposure of internal organs to possible contaminants.

**[0003]** Generally, minimally invasive surgeries utilize scopes, such as laparoscopes, that permit remote visualization of a surgical site within a patient's body while the surgical procedure is being performed. During a laparoscopic procedure, the patient's abdominal or pelvic cavity is accessed through two or more relatively small incisions rather than through a single large incision that is typical in a conventional surgery. Surgical scopes, such as laparoscopes, usually consist in part of a rigid or relatively rigid rod or shaft having an objective lens at one end and an eyepiece and/or integrated visual display at the other. The scope may also be connected to a remote visual display device or a video camera to record surgical procedures.

**[0004]** In laparoscopic surgeries, the abdomen is typically inflated with a gas through the use of an insufflator, to distend the abdominal space by elevating the abdominal wall above the internal organs and thereby create a sufficient working and viewing space for the surgeon. Carbon dioxide is usually used for insufflation, though other suitable gases may also be used. Conventional insufflators are adapted to cycle on and off to maintain a preset and suitable pressure within the patient's body cavity.

**[0005]** The local environment within a patient's abdominal space is generally rather warm and humid, and the use of devices such as harmonic scalpels and other cutting and coagulating devices generate mist, smoke, and other debris that is released into the surgical field and often becomes suspended throughout the expanded abdominal space. Additionally, blood, bodily fluids, pieces of tissue, fat or other bodily material may come in contact with or even attach to the lens. As a result of these conditions, visualization through the scope can be significantly diminished. Typically, the only solution to fogging and debris collection on the lens is removal of the scope from the body cavity and defogging or cleaning the lens by wiping it with a cloth, warming the scope tip, or utilizing another defogging method. The need to remove the scope to defog and remove debris from the lens is inconvenient for the scope operator and the surgeon and can interrupt and undesirably prolong surgical procedures.

### SUMMARY

**[0006]** Embodiments of a device for maintaining visualization with a surgical scope are provided. The embodiments of

the device are adapted to shield, defog or clean the lens of the surgical scope while the surgical scope is being used to perform a surgical procedure within a patient's body.

**[0007]** Additional features and advantages of the invention will be set forth in part in the description which follows, and in part will be obvious from the description, or may be learned by practice of the invention. The features and advantages of the invention will be realized and attained by means of the elements and combinations particularly pointed out in the appended claims.

**[0008]** It is to be understood that both the foregoing general description and the following detailed description are exemplary and explanatory only and are not restrictive of the invention, as claimed.

**[0009]** The accompanying drawings, which are incorporated in and constitute a part of this specification, illustrate several embodiments of the invention, and together with the description, serve to explain the principles of the invention.

### BRIEF DESCRIPTION OF THE DRAWINGS

**[0010]** The present invention may be more readily understood by reference to the following drawings wherein:

**[0011]** FIG. 1 is a perspective view of a laparoscope;

**[0012]** FIG. 2A is a perspective view of a first embodiment of a the laparoscope view optimizer in use with the laparoscope of FIG. 1;

**[0013]** FIG. 2B shows a side view of another exemplary embodiment of the view optimizer 200 of the present application;

**[0014]** FIG. 3 is an exploded perspective view of the view optimizer of FIG. 2;

**[0015]** FIG. 4A is a magnified perspective view of the guard tube of the view optimizer of FIG. 2A surrounding the laparoscope of FIG. 1;

**[0016]** FIG. 4B is a magnified perspective view of the guard tube and exhaust ring of the view optimizer of FIG. 2A surrounding the laparoscope of FIG. 1;

**[0017]** FIG. 4C is a magnified perspective view of the guard tube, exhaust ring and end ring of the view optimizer of FIG. 2A surrounding the laparoscope of FIG. 1;

**[0018]** FIG. 5A is a magnified front perspective view of the adapter ring of the view optimizer of FIG. 2;

**[0019]** FIG. 5B is a magnified rear perspective view of the adapter ring of the view optimizer of FIG. 2;

**[0020]** FIG. 6 is an alternate perspective view of the view optimizer of FIG. 2;

**[0021]** FIG. 7 shows results of analysis of humidity and fogging; and

**[0022]** FIG. 8 shows results of evaluation of effect of introduction of compliant accumulator on flow across laparoscope lens.

### DETAILED DESCRIPTION OF THE INVENTION

**[0023]** The present invention will now be described with occasional reference to specific embodiments of the invention. This invention may, however, be embodied in different forms and should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will fully convey the scope of the invention to those skilled in the art.

**[0024]** Except as otherwise specifically defined herein, all terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this

invention belongs. The terminology used in the description of the invention herein is for describing particular embodiments only, and is not intended to be limiting of the invention. As used in the description of the invention and the appended claims, the singular forms "a," "an," and "the" are intended to include the plural forms as well, unless the context clearly indicates otherwise.

[0025] Unless otherwise indicated, all numbers expressing quantities, properties, and so forth as used in the specification and claims are to be understood as being modified in all instances by the term "about." Accordingly, unless otherwise indicated, the numerical properties set forth in the following specification and claims are approximations that may vary depending on the desired properties sought to be obtained in embodiments of the present invention. Notwithstanding that the numerical ranges and parameters setting forth the broad scope of the invention are approximations, the numerical values to the extent that such are set forth in the specific examples are reported as precisely as possible. Any numerical values, however, inherently contain certain errors necessarily resulting from error found in their respective measurements.

[0026] The present application relates generally to various embodiments of a device for use with surgical scopes. More particularly, this application relates to various embodiments of view optimizer devices of varying constructions for use with laparoscopes, the view optimizer device being adapted to shield, defog or clean the lens of the laparoscope while the laparoscope is being used to perform a surgical procedure within a patient's body. Though the device is referred to herein as a view optimizer, it will be appreciated that its designation as such is not intended to limit in any way its use and operation for a variety of purposes as further described herein in addition to controlling, improving and maintaining and improving desirable visualization of a laparoscopic surgical field.

[0027] Referring to FIG. 1, a perspective view of an exemplary, conventional laparoscope 100 is shown. The laparoscope 100 has an elongated cylindrical main body 110 having a distal end 120 and an imaging end 130. The main body 110 of the laparoscope may be either rigid or flexible, depending on the procedure the laparoscope is being used to perform, as well as the type of laparoscope being utilized. An objective lens (not shown in FIG. 1) is disposed within the distal end 120 of the main body 110, the objective lens being generally transverse to the longitudinal axis of the main body 100. Generally, laparoscope 100 includes an illumination system, which can be any type of suitable illumination system, such as a network of fiber optic cables, housed within the main body 110 of laparoscope 100 for illuminating the surgical site being imaged by the operative lens of the laparoscope. Laparoscope 100 includes an illuminator connector 140 for the connection of an external light source, which supplies the illumination system with illuminating light.

[0028] The imaging end 130 of the main body 110 includes an eyepiece 150. Conventional laparoscopes include an image transmission system (not shown in FIG. 1), which can be any type of suitable image transmission systems, such as a system of lens, lens rods or other optical components, housed within the main body 110 of the laparoscope for transmitting the image viewed by the objective lens to the eyepiece 150, thus allowing the scope operator to view within the patient's abdominal cavity. It is well known in the art that a video camera or other visual display device can be operatively connected to the eyepiece 150 or other portion of the laparo-

scope 100 to convert the optical signal into a video signal, which is ultimately processed by a video processing means to produce a video image on a monitor or for storage on magnetic tape or other storage media. It should be understood that the laparoscope discussed above is representative of conventional laparoscopes. It will be appreciated that in its various embodiments, the view optimizer device of the present application can be used in connection with a variety of laparoscopes or other surgical scopes of varying constructions.

[0029] Referring now to FIG. 2, a perspective view of an exemplary embodiment of the view optimizer 200 of the present application is represented. As shown in FIG. 2, the view optimizer 200 generally includes a lens guard 210 and a flow controller 220. The lens guard 210 of the illustrated embodiment is adapted to receive a portion of the laparoscope 100, most particularly the distal end 120 thereof, and a portion of the main body 110 of the laparoscope. The lens guard 210 of the illustrated embodiment is in the form of a substantially continuous cylindrical sheath or tube that encloses a significant portion of the body of the laparoscope 100. It will be appreciated that in alternate embodiments, the lens guard 210 may be discontinuous, such that it may be formed of an open lattice or matrix that does not fully enclose the body of the laparoscope. As will be described further herein, the common structural features of the various embodiments of the lens guard 210 will be adapted to allow communication between the lens guard 210 of the view optimizer 200 at the distal end 120 of the laparoscope, on the one hand, and the flow controller 220 of the view optimizer 200 on the body 110 of the laparoscope near its imaging end 130, on the other hand, so as to provide for the functions of the view optimizer. Referring again to FIG. 2, the illustrated view optimizer 200 is adapted to deliver to the objective lens of the laparoscope at least one fluid selected from, for example, a liquid, such as water or saline, and a gas, such as CO<sub>2</sub> or air, to prevent the contact of material with the objective lens of the laparoscope or to defog or clean the objective lens of the laparoscope without the need to remove the laparoscope from the surgical field.

[0030] According to some embodiments, the view optimizer 200 is adapted to deliver a stream of fluid to the objective lens of the laparoscope so as to create a current passing over the face of the lens that transports moisture located on or near the lens away from the lens, thus preventing moisture from adhering to the lens. In additional embodiments, the view optimizer 200 delivers a stream of fluid to the objective lens at a temperature that is adapted to help ensure that the temperature of the objective lens does not fall to a point that is at or below the dew point temperature within the patient's abdominal cavity, thus preventing condensation from forming on the lens. Finally, in yet additional embodiments, the view optimizer 200 is adapted to deliver a stream of generally anhydrous fluid to the objective lens. In such embodiments, the generally anhydrous fluid serves to attract and absorb moisture particles located on or near the lens and carry the moisture away from the lens with the flow of fluid. Medical grade CO<sub>2</sub> for use with conventional insufflators is typically 99% pure, that is, no more than 1% of the gas is other than CO<sub>2</sub>, and such medical grade CO<sub>2</sub> generally has a maximum moisture content of 25 parts per million by volume.

[0031] It should be understood that additional embodiments of the view optimizer 200 may perform only one of the above-described functions or any combination of these functions. Based on testing that was conducted in connection with the view optimizer 200 of the illustrated embodiment, when

the temperature within the patient's abdomen was approximately 102.9° F. and the relative humidity within the patient's abdomen was 76%, the delivery of a stream of fluid to the objective lens of the laparoscope **100** at a flow rate of equal to or greater than 0.07 liters per minute proved to be effective for defogging the lens (and/or preventing the fogging of the lens). It should be understood, however, that a variety of different flow rates will be effective for defogging the lens depending on the temperature and the moisture content of the gas being supplied by the insufflator and the temperature and relative humidity of the patient's abdomen as well as other variables. As a way of illustrating the defogging effects of the view optimizer **200** according to one embodiment, the following information was collected regarding the dew point temperature of the objective lens of the laparoscope when located within the patient's abdominal cavity.

**[0032]** According to some embodiments, the view optimizer **200** is adapted to deliver a stream of one or more fluids across the objective lens of the laparoscope **100** to deflect blood, bodily fluids, pieces of tissue, fat or other bodily material that come within the vicinity of the objective lens. The stream of fluid may be either continuous or intermittent. In addition, according to some embodiments, the view optimizer **200** is adapted to deliver a burst or bolus of gas and/or liquid to the objective lens of the laparoscope when the scope operator desires. This burst or bolus of gas and/or liquid serves, at least in part, to facilitate removal of blood, bodily fluids, pieces of tissue, fat or other bodily material on the objective lens. In this manner, the scope operator can deliver a burst of gas or liquid to the objective lens to remove a piece of material or droplet of liquid, which was otherwise unable to be removed from the objective lens. It should be understood that additional embodiments of the view optimizer **200** may perform only one of the above-described functions or any combination of these functions.

**[0033]** The gas that is delivered to the objective lens of the laparoscope **100** by the view optimizer **200** is supplied by a conventional insufflator. Of course, it should be understood that the view optimizer **200** of this application could be supplied with gas via another external source other than an insufflator, or could include a gas supply device incorporated within or provided with the view optimizer **200**, or by combinations of gas sources. Conventional insufflators are designed to insufflate a patient's abdominal cavity until a pre-determined suitable pressure for the operative procedure is reached. Once this pre-determined pressure is reached, conventional insufflators are designed to cease insufflating the cavity. Typical insufflators are designed to resume insufflation once the pressure in the cavity drops below the pre-determined pressure due to the leakage of gas through the trocars being used, through incisions in the patient's body cavity, or by some other means. In this manner, conventional insufflators typically continuously cycle between an insufflation state and a static state while being utilized during an operative procedure to maintain a pre-determined pressure within the patient's abdominal cavity.

**[0034]** According to various embodiments, the view optimizer **200** delivers gas to the lens of the laparoscope so as to provide a guard or shield to deflect liquid and particulate debris and prevent it from contacting the lens. According to some embodiments, the gas delivery is intermittent. According to other embodiments, such as the embodiment illustrated in FIG. 2, the flow of gas is essentially continuous. As such, the flow of gas during operation of the view optimizer **200**

flows constantly, with delays of flow that are of a duration not greater than 5 seconds. Accordingly, in various embodiments wherein the flow of gas is essentially continuous, delays in flow are of a duration that is not greater than about 0.2, 0.4, 0.6, 0.8, 1.0, 2, 3, 4, or 5 seconds. As is further described herein, the embodiment of the view optimizer **200** illustrated in FIG. 2A is supplied with gas by the insufflator comprising one or more of a variety of means to permit an essentially uninterrupted supply of gas to be directed across the objective lens of the laparoscope **100**. Accordingly, the illustrated embodiment includes a leakage or venting of gas from the body cavity so as to ensure continuous gas flow from the insufflator. This leak allows gas to exit the patient's abdominal cavity as necessary to ensure that the insufflator remains substantially in an insufflation state, thus supplying the view optimizer **200** with a generally continuous supply of gas.

**[0035]** The leak of the illustrated embodiment is created by a vent or vents defined within the lens guard **210**. The leak of the illustrated embodiment of the view optimizer **200** is a controlled leak that can be controlled by a user of the scope through the use of a valve or other control mechanism. The valve provided to control the leak could be a simple two-state, on/off valve or it could be a multi-state, variable valve that allows the flow rate of the leak to be adjusted. The valve or other control mechanism could be either manually operated or automated, or under electronic control. Thus, it should be understood that the leak created by the view optimizer **200** could be provided in a manner that is not controlled by a user.

**[0036]** The view optimizer **200** of the illustrated embodiment provides a leak that has a flow rate that is generally between zero (0) and eight (8) liters per minute, and approximately 7.8 liters per minute, wherein two of the six channels are for exhaust venting (as discussed further herein in connection with FIG. 4. Accordingly, in various embodiments, the flow rate of the leak is about 0, 0.5, 1, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0, 4.5, 5.0, 5.5, 6.0, 6.5, 7.0, 7.5, 8.0 liters per minute. However it should be understood that additional embodiments of the view optimizer **200** may provide a leak having a variety of different flow rates, in which case such flow rates may exceed 8, 9, 10, 12, 14, 16, 18, or more liters per minute, or increments thereof. As a way of illustrating the effect of the leak provided by the view optimizer **200** of the illustrated embodiment on the insufflator, the following information was collected regarding the cycling intervals of a conventional insufflator during an operative procedure when a leak was provided by the view optimizer as compared to the insufflator operating without a leak being provided.

**[0037]** In addition, while the leak created by the view optimizer **200** of the illustrated embodiment is a passive leak that relies on the pressure within the patient's body cavity to expel gas from within the cavity, alternative embodiments of the view optimizer could be augmented by the utilization of a vacuum or other suction means to create a suction force that actively draws gas out from within the patient's body cavity. In such embodiments, the leak could likewise be under the control of the user, or otherwise under the control of an automated source or an electronic control.

**[0038]** Such embodiments that provide a vacuum or other suction means, may provide a suction force between zero (0) inches of mercury (in. Hg) and twenty six (26) inches of mercury (in. Hg). Accordingly, in various embodiments, the suction force provided is about 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25 or 26 inches of mercury (in. Hg). In some embodiments the suction

force provided by the vacuum or other suction means of such embodiments is between twelve (12) inches of mercury (in. Hg) and fourteen (14) inches of mercury (in. Hg). However it should be understood that additional embodiments of the view optimizer 200 may provide a suction force having a variety of values that exceed 26 inches of mercury.

[0039] In additional embodiments of the view optimizer 200, the controlled leak could be created in alternative ways other than vents defined within the lens guard 210. For example, the leak could be created by a vent defined within the interface between the view optimizer 200 and the trocar that receives the view optimizer 200. For instance, the outer diameter of the lens guard 210 could be adapted to create a gap between the outer diameter of the lens guard 210 and the inner diameter of the trocar opening, thus, creating a leak. In addition, one or more notches, indentations or other openings could be defined within the portion of the view optimizer 200 that interfaces with the trocar, or, alternatively, within a portion of the trocar that interfaces with the view optimizer 200, to create a gap through which gas could escape. Additional embodiments may include one or more notches, indentations or openings that extend along the entire length of the lens guard 210, thereby, creating a leak between the lens guard 210 and the trocar. As discussed previously, it should be understood that this leak located at the interface between the view optimizer 200 or lens guard 210 and the trocar could be controlled with the use of a valve or other control mechanism. In addition, this leak could be a passive leak or could utilize a vacuum or other pumping means to actively draw gas out from within the patient's body cavity. It will be appreciated that the construction of the lens guard 200 may be adapted such that whether it is formed as continuous sheath, or is formed of two or more portions, it is nevertheless adapted to allow for the introduction and control of a leak according to the various embodiments described herein.

[0040] While the creation of a leak helps to ensure that the insufflator provides the view optimizer 200 with a generally continuous supply of gas, the leak can also serve to remove moisture from within the patient's body cavity, thereby, decreasing the humidity within the cavity. Humidity levels in a laparoscopic surgical field can range from below 50% to close to 100% relative humidity; in most cases, the range is from about 75% to 99%, and most typically from about 85% to about 95%. Thus, the humidity within the abdomen can exist from less than 50%, to 55, 60, 65, 70, 75, 80, 85, 90, 95 and 100%, and increments thereof. Reduction of the humidity within the patient's body cavity serves to diminish the likelihood that the objective lens of the laparoscope 100 will become fogged when it is within the patient's body cavity. In addition, the leak can also help to remove smoke and mist generated from the use of a harmonic scalpel, and/or other particulate matter that is suspended in the gas within the patient's body cavity. This removal of airborne matter from within the patient's body cavity serves to ensure that the visibility through the objective lens of the laparoscope 100 is maintained.

[0041] It should be understood that the gas exiting the patient's body cavity via the leak created by the view optimizer 200 could be filtered in various embodiments. This filtering process could serve to remove blood, bodily fluids, or other matter from the gas exiting the patient's body cavity, thus, preventing these potential contaminants from entering the air within the operating room. It is beneficial to remove such matter from the escaping gas to prevent anyone in the

operating room from inhaling such matter. It should also be understood that the gas exiting the patient's body cavity via the leak could be recycled for re-delivery into the patient's body cavity by the insufflator or the view optimizer 200. In addition, baffles or other muffling means could be incorporated with the vents provided by additional embodiments to muffle the sound of gas exiting the vents. Finally, it will be understood that in other embodiments, wherein the supply of fluid is to be intermittent, that there is not a need for a leak.

[0042] Referring again to FIG. 2, the lens guard 210 of the illustrated embodiment of the view optimizer 200 is an elongated, hollow cylindrical tube. The lens guard 210 has a distal end 212 and a proximal end 214. The distal end 212 of the lens guard 210 is adapted to surround the distal end 120 of the laparoscope 100. According to the illustrated embodiment, the distal end 212 of the lens guard 210 does not cover or fully enclose the distal end 120 of the laparoscope. It will be appreciated that in some alternate embodiments, a lens guard 210 may include structure that fully encloses the distal end 120 of the laparoscope, and as such is formed of a material that permits visualization. The proximal end 214 of the lens guard 210 is joined to the flow controller 220 of the view optimizer 200. The flow controller 220 of the view optimizer 200 of the illustrated embodiment is adapted to support and enclose components of the view optimizer 200. The flow controller 220 of the view optimizer 200 supplies the lens guard 210 with gas and/or liquid via one or more of conduits that connect to lens guard 210. The flow controller 220 receives gas and/or liquid from one or more exterior sources via air inlet 230 and liquid inlet 240 and delivers the gas and/or liquid to the lens guard 210. The flow controller 220 of the illustrated embodiment includes a gas/liquid flow actuator/regulator 250 for the actuation and/or regulation of the flow of gas and/or liquid to the lens guard 210. The flow controller 220 of the illustrated embodiment includes a burst flow actuator/regulator 260 for the actuation and/or regulation of the delivery of a burst or bolus of gas and/or liquid to the lens guard 210, as described above.

[0043] FIG. 2A shows the lens guard 210 and the flow controller 220 of the view optimizer 200 joined together as a unitary construction. It should be understood that the lens guard 210 and the flow controller 220 could be provided as two or more separate pieces that are used remotely from one another and not joined together as a unitary construction. FIG. 2B shows a side view of another exemplary embodiment of the view optimizer 200 of the present application. In this embodiment, the view optimizer 200 is in two separate pieces (the prime designation, e.g. 210', is used to reference features that are common between the embodiments depicted in FIG. 2A and FIG. 2B). The lens guard 210' is attached at its proximal end 214 to the laparoscope 100, and comprises a vent actuator 280, and a fluid conduit 270 that is in communication with the flow controller 220' (connection not shown). The flow controller 220' is depicted as an ergonomic device to be grasped in an operator's hand, with a flow actuator/regulator 250' adapted to be depressed by the operator's thumb, and a burst flow actuator/regulator 260' adapted to be depressed by the flexion of the operator's fingers, to deliver the flow of gas or liquid from one or more inlet sources (not shown) through the fluid conduit 270, for delivery to the objective lens of the scope through distal end 212 of the lens guard 210. In the depicted embodiment, the vent actuator 280 is under the control of the scope operator, and may be adjusted as needed to assist in maintaining visualization. Of course it will be

understood that in alternate embodiments, one or more of these actuators may be eliminated, and their locations may be switched, or all actuators may be located on the flow controller 220' or may be located at yet another controller, such as a separate foot activated controller (not shown). In yet other embodiments, the lens guard 210 and the flow controller 220 could be provided as two or more separate pieces that are assembled for use. While the lens guard 210 and the flow controller 220 of the illustrated embodiment are formed from plastic, other suitable materials, such as metal or a composite material, or combinations of these could also be used.

[0044] Referring to FIG. 3, the view optimizer 200 will now be described with more particularity. As mentioned earlier, the lens guard 210 is an elongated, cylindrical tube. However, it should be understood that the lens guard 210 is not limited to this shape and configuration and other suitable shapes and configurations could also be used in additional embodiments. Examples of additional constructions have been previously described. Examples of additional cross-sectional shapes that could be used for the lens guard 210 include, but are not limited to, rectangular, triangular, oval, etc. The lens guard 210 can have any shape or configuration which allows it to surround the distal tip 120 of the laparoscope 100. Additional embodiments of the view optimizer 200 may include a lens guard which has an angled portion to correspond with scopes with angled portions, such as 450 or 300 angled scopes. The lens guard 210 of the illustrated embodiment is substantially rigid. However, it should be understood that additional embodiments of the view optimizer may include a flexible lens guard, which is adapted for use with a flexible scope. The lens guard 210 of the embodiment illustrated in FIG. 2A is fashioned from plastic, but other suitable materials such as metal or a composite material or combinations of these could also be used.

[0045] While the view optimizer 200 of the illustrated embodiment includes a lens guard 210 that surrounds and encloses the entire length of the laparoscope 100, it should be understood that the lens guard 210 of the view optimizer 200 could have any shape, construction or configuration that allows it to deliver gas and/or liquid to the objective lens of the laparoscope 100. For example, in alternative embodiments the lens guard 210 could be formed of one or more channels, tubes or conduits adapted to deliver gas and/or liquid to the objective lens of the laparoscope 100. The channels, tubes or conduits of such embodiments of the lens guard 210 could be supported by a rigid or flexible framework. The channels, tubes or conduits of such embodiments could also be fastened to the laparoscope 100 itself, either removably or permanently, by one or more fasteners, such as straps, ties, adhesives, clips, etc. In such embodiments, additional methods of sealing the interface between the view optimizer 200 and the trocar may be employed. For example, the portion of the view optimizer 200 that interfaces with the trocar may be a member that serves to form a seal with the trocar while the portion of the view optimizer 200 that is inserted into the patient's body cavity and delivers gas and/or liquid to the objective lens of the laparoscope could be one or more channel, tube or conduit and/or a rigid or flexible framework. In addition, the lens guard 210 of additional embodiments could be adapted to surround and enclose only portions of the laparoscope 100, leaving other portions of the laparoscope 100 un-enclosed.

[0046] As shown in FIG. 3, the lens guard 210 of the illustrated embodiment includes an adapter ring 302, a guard tube 304, an exhaust ring 306, and an end ring 308. Referring to

FIG. 4A, the guard tube 304 is shown with more particularity (the exhaust ring 306 and end ring 308 of the lens guard 210 are not present in FIG. 4A to better illustrate the construction of the guard tube 304). As shown in FIG. 4A, the guard tube 304 is a hollow, cylindrical tube adapted to surround the laparoscope 100. The guard tube 304 has an outer wall 510 that defines a hollow space. As shown in FIG. 4A, channels 512 are defined within the outer wall 510 and extend the length of the guard tube 304. The channels 512 are adapted to allow for the travel of gas and/or fluid along the length of the guard tube 318. The guard tube 304 depicted in the figures includes six channels 512, each having one or more functions. However, it should be understood that additional embodiments of the view optimizer may include any number of channels 512 defined within the guard tube 318, such as, for example, a single channel for multiple functions, or two or more channels each having distinct functions. The channels 512 may have a variety of sizes, shapes and configurations that allow for the passage of gas and/or liquid. The guard tube 318 of the illustrated embodiment shown in FIG. 5 has two channels 512 for the passage of exhaust gas from the interior of the patient's body cavity, and is suitable for providing a controlled leak. The illustrated embodiment also includes two channels dedicated to delivery of gas from the insufflator to the objective lens of the laparoscope 100, and one channel for the passage of the liquid to the objective lens of the laparoscope. Additional embodiments of the view optimizer 200 may include guard tubes 304 that have any number of channels 512 dedicated to any combination of gas for delivery to the objective lens of the laparoscope, liquid for delivery to the objective lens of the laparoscope, and/or exhaust gas. As mentioned previously, various additional embodiments of the view optimizer 200 may utilize both gas and liquid or only one of gas or liquid for delivery to the objective lens of the laparoscope. In some embodiments, the view optimizer may lack exhaust channels. Generally, depending on the intended functionality of the lens guard, the one or multiple channels 512 of the guard tube 304 will be suitably adapted.

[0047] Referring to FIG. 4B, the guard tube 304 and exhaust ring 306 of the lens guard 210 are shown in use with a laparoscope 100 (the end ring 308 of the lens guard 210 is not shown in FIG. 4B to better illustrate the construction of the exhaust ring 306). The exhaust ring 306 is a hollow, cylindrical piece adapted to surround and enclose a portion of the laparoscope 100. As shown in FIG. 4B, the guard tube 304 and the exhaust ring 306 of the view optimizer 200 are attached together. The guard tube 304 and the exhaust ring 306 can be attached together in a variety of different ways, such as by adhesives, screws, tabs and slots, etc. In addition, the guard tube 304 and exhaust ring 306 could be formed together as a unitary construction.

[0048] The exhaust ring 306 has an outer wall 514 which defines a hollow space. Exhaust vents 516 are defined within the outer wall 514 of the exhaust ring 306. As shown in FIG. 4B, the guard tube 304 and the exhaust ring 306 abut against one another when the lens guard 210 is assembled. The exhaust vents 516 defined within the outer wall 514 of the exhaust ring 306 are adapted to form openings into two of the channels 512 of the guard tube 304 that are dedicated to the passage of exhaust gas from within the patient's body cavity in conjunction with the leak function of the view optimizer 200 of the illustrated embodiment. The pressure within the patient's body cavity is greater than the pressure within the channels 512 of the guard tube 304. Accordingly, gas from

within the patient's body cavity will enter the exhaust vents **516** and travel through the channels **512** defined within the guard tube **304** out of and away from the patient's body cavity. While the embodiment of the exhaust ring **306** illustrated in FIG. **4B** includes two exhaust vents **516**, additional embodiments of the view optimizer **200** may include exhaust rings **306** with any number of exhaust vents. The exhaust vents **516** may have any shape, size and configuration which allows gas to enter the guard tube **306** or some other portion of the view optimizer **200**. As discussed above, additional embodiments of the view optimizer **200** may lack a controlled leak function, thus, such embodiments of the view optimizer **200** will not include exhaust vents **516**.

[0049] Referring again to FIG. **4B**, channels **518**, **520**, **521** and **522** are defined within the outer wall **514** of the exhaust ring **306** and extend through the length of the exhaust ring **306**. The channels are adapted to allow for the travel of either gas and/or liquid along the length of the exhaust ring **306**. When the lens guard **210** is assembled, each of the channels **518**, **520**, **521** and **522** of the exhaust ring **306** align with a channel **512** of the guard tube **304** to allow for the passage of gas and/or liquid therethrough. While the exhaust ring **306** of the illustrated embodiment includes four channels, additional embodiments of the view optimizer may include exhaust rings **306** with any number of channels.

[0050] As depicted, channel **518** of the exhaust ring **306** of the illustrated embodiment is adapted for the passage of liquid for delivering to the objective lens of the laparoscope **100**. Channels **520**, **521** are adapted for the passage of gas for delivery to the objective lens of the laparoscope **100**. Channel **522** of the exhaust ring **306** of the illustrated embodiments is not operative to allow for the passage of either gas and/or liquid. However, in additional embodiments, channel **522** could be functional. Channel **522** could act as an exhaust channel for both fluid and gas. While the exhaust ring **306** includes four channels, it should be understood that additional embodiments of the exhaust ring **306** may include any number of channels. The channels **518**, **520**, **521** and **522** may have a variety of sizes, shapes and configurations. The channels **518**, **520**, **521** and **522** can have any size, shape and configuration that allows for the passage of gas and/or liquid. As mentioned previously, various additional embodiments of the view optimizer **200** may utilize both gas and liquid or one of gas or liquid for delivery to the objective lens of the laparoscope for cleaning and/or defogging. Accordingly, such factors will determine the usage and number of channels as well as the construction, size, shape and configuration of the end ring **308** of additional embodiments of the view optimizer **200**.

[0051] As shown in FIG. **4B**, the exhaust ring **306** includes fastener openings **523** for use in the attachment of the end ring **308**. As shown in FIG. **4C**, the exhaust ring **306** and the end ring **308** of the view optimizer **200** are attached together. The exhaust ring **306** and the end ring **308** of the illustrated embodiment are attached together by projections (not shown) which extend from the end ring **308** and are received within the fastener openings **523** of the exhaust ring **306**. However, it should be understood that the end ring **308** and the exhaust ring **306** can be attached together in a variety of different ways, such as by adhesives, screws, tabs and slots, etc. In addition, the end ring **308** and exhaust ring **306** could be formed together as a unitary construction.

[0052] Referring now to FIG. **4C** the guard tube **304**, exhaust ring **306** and end ring **308** are shown in use with a

laparoscope **100**. The end ring **308** is attached to the exhaust ring **306** and extends beyond the end of the laparoscope **100**. This extension of the end ring **308** beyond the distal end **120** of the laparoscope **100** facilitates delivery of fluid to the lens, as further described herein, and helps to shield the objective lens from contacting objects or tissue, either within the patient's body cavity or outside of it, such as within the passageway within a trocar, that may soil, smudge, smear or adhere to the objective lens of the laparoscope. For example, conventional trocars include a seal assembly that consists of a plurality of flaps that create a seal with objects that are inserted through the trocar. These flaps of the trocar seal can become soiled with blood, bodily fluids, pieces of tissue, fat or other bodily material during an operative procedure. The extension of the end ring **308** beyond the distal end **120** of the laparoscope **100** serves to contact these flaps prior to the laparoscope **100** as the laparoscope **100** and view optimizer **200** are being inserted through the trocar, thereby deflecting the soiled flaps away from contacting the objective lens of the laparoscope **100**, and thus, preventing any blood, bodily material or other matter that is on the flaps from contacting and/or dirtying the objective lens. Likewise, the extension of the end ring **308** beyond the distal end **120** of the laparoscope also serves to deflect objects, such as internal organs or other tissue or fat, from contacting the objective lens of the laparoscope **200** when within the patient's body cavity.

[0053] According to various embodiments, the end ring **308** portion of the view optimizer **200** may extend beyond the end of the laparoscope from about 0 mm to about 7 mm. Accordingly, in various embodiments, the end ring **308** portion of the view optimizer **200** may extend beyond the end of the laparoscope from about 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5, 5.5, 6, 6.5, 7 mm or more. It should be understood that additional embodiments of the view optimizer **200** may not include an end ring **308** or other structure that extends beyond the distal end **120** of the laparoscope **100**.

[0054] The end ring **308** is adapted to partially enclose the distal end **120** of the laparoscope **100**. The end ring **308** has a main wall **524**. Passageways **526**, **528**, **530** and **532** are defined within the main wall **524** of the end ring **308**. Passageways **526**, **528**, **530** and **532** are adapted to direct the flow of gas and/or liquid exiting the channels **518**, **520**, **521** of the exhaust ring **306** across the operative lens of the distal end **120** of the laparoscope. The passageways **526**, **528**, **530** and **532** of the illustrated embodiment of the view optimizer **200** direct at least a portion of the flow of gas and/or liquid across the face of the objective lens. In the sheath assembly **200** of the illustrated embodiment, passageway **526** is adapted to direct the flow of liquid from channel **518** of the exhaust ring **306** across the objective lens of the laparoscope **100**. Channels **528**, **530** of the illustrated embodiment are adapted to direct the flow of the gas from channels **520**, **521** of the exhaust ring **306** across the objective lens of the laparoscope **100** to deflect gas and liquid from the lens, defog the objective lens as well as to remove moisture or material from the surface of the objective lens. Channels **528**, **530** are also adapted to direct at least a portion of the gas from channels **520**, **521** in a path that projects forward from the objective lens (as viewed in FIG. **4C**) at an angle relative to the objective lens. The flow of the gas that is directed forward from the distal end **120** of the laparoscope further serves to deflect away smoke, particulate, blood, bodily fluid, moisture, tissue, fat, or other material within the patient's body cavity from contacting the objective lens of the laparoscope **100**. Accordingly, as the laparoscope

**100** is inserted into the patient's body cavity and/or moved within the cavity, this forwardly projecting flow of gas serves to deflect away blood or other material that approaches the objective lens.

**[0055]** It should be understood that additional embodiments of the view optimizer **200** could direct all of the gas and/or liquid across the objective lens in a path that is generally parallel to the objective lens or could direct all of the gas and/or liquid in a path projecting forward and away from the distal end **120** of the laparoscope at an angle relative to the objective lens, or could direct all or a portion of the gas and/or liquid in a path projecting toward the distal end **120** of the laparoscope **100** at an angle relative to the objective lens, or any combination of parallel flow and angled flow.

**[0056]** Embodiments of the view optimizer **200** may provide for the delivery of gas and/or liquid in a path having any angle relative to the objective lens between  $0^\circ$  and  $90^\circ$  or between  $0^\circ$  and  $-90^\circ$ , wherein the negative designation refers to paths directed toward the lens. In some embodiments, fins or louvers are provided to direct the flow of the gas and/or liquid in a variety of different paths each having a different angle relative to the objective lens, thereby, creating a fanned out flow of gas and/or liquid. According to various embodiments, the length of extension of the end ring **308** portion of the view optimizer **200** that extends beyond the end of the laparoscope from about 0 mm to about 7 mm may comprise one or more passageways that deliver a fluid stream at one or a range of positions along the length of the end ring **308**. According to such embodiments, the passageways may be positioned at the base of the end ring **308**, near to the lens of the scope, or at the distal end of the end ring **308**, farthest away from the lens, or at one or more locations in between. And according to such various embodiments, the passageways may be configured to direct a narrow stream of fluid, or may be configured to direct a fan of fluid at various angles.

**[0057]** The embodiment depicted in FIG. 4C is configured with an end ring **308** that extends about 2 mm from the end of the laparoscope and is configured to deliver a fan of air at an angle of about  $30^\circ$ , thus the distance of the flow path nearest the lens at the point of the passageway is about 0 mm and the distance of the flow path nearest the lens at the opposite side of the lens is about 8 mm from the lens. Variation of the length of the end ring, distance of the passageway from the lens, angle or angles of flow may vary, such that the distance of the nearest flow path from the lens may range from 0 mm to more than 15 mm, and in some embodiments the flow path may be directed at an angle toward the lens.

**[0058]** The end ring **308** of additional embodiments have a variety of sizes, shapes and configurations. The end ring **308**, can have any size, shape or configuration that allows it to direct gas and/or liquid across the face of the objective lens of the laparoscope. While the end ring **308** of the illustrated embodiment only partially encircles the distal end **120** of the laparoscope **100**, it should be understood that additional embodiments of the view optimizer **200** may include an end ring **308** that completely encircles the distal end **102** of the laparoscope **100**. As mentioned previously, various additional embodiments of the view optimizer **200** may utilize both gas and liquid or one of gas or liquid for delivery to the objective lens of the laparoscope for cleaning and/or defogging. In addition, additional embodiments of the view optimizer **200** may not include a controlled leak function. Accordingly, such

factors will affect the construction, size, shape and configuration of the end ring **308** of additional embodiments of the view optimizer **200**.

**[0059]** Referring again to FIG. 3, an adapter ring **302** is located at the proximal end **214** of the lens guard **210**. The adapter ring **302** is adapted to mount the lens guard **210** to the main body. The adapter ring **302** can have any size, shape or configuration that allows it to mount the lens guard **210** to the flow controller **220**. In addition, as mentioned previously, the lens guard **210** and flow controller **220** of additional embodiments may be formed as a unitary piece or may also be located remotely from one another and not directly connected to one another.

**[0060]** As shown in FIG. 5A, the adapter ring **302** has a generally cylindrical shape with a guard tube opening **610** defined through it. The guard tube opening **610** is adapted to receive the guard tube **304**. The guard tube opening **610** of the adapter ring has an inner rim **620**. When the guard tube **304** is inserted into the adapter ring, the guard tube **304** abuts against the inner rim **620**. In this manner, the inner rim **620** helps to properly locate the guard tube **304** within the adapter ring **302** and prevents the guard tube **304** from passing completely through the adapter ring **302**. Several channels **630** are defined within the inner rim **620** of the adapter ring and pass through the length of the adapter ring **302**. The adapter ring **302** of the illustrated embodiment of the view optimizer has six channels **630** to coincide with the six channels **512** of the guard tube **304**. When the guard tube **304** is secured within the adapter ring **302**, the channels **512** of the guard tube **304** align with the channels **630** of the adapter ring, to allow for gas and/or liquid to flow from the channels **512** of the guard tube to the coinciding channels **630** of the adapter ring **302** and vice versa.

**[0061]** While the adapter ring **302** of the illustrated embodiment includes six channels **630**, it should be understood that additional embodiments of the adapter ring **302** may include any number of channels **630**. The channels **630** may have a variety of sizes, shapes and configurations. The channels **630** can have any size, shape and configuration that allows for the passage of gas and/or liquid. As mentioned previously, various additional embodiments of the view optimizer **200** may utilize both gas and liquid or one of gas or liquid for delivery to the objective lens of the laparoscope for cleaning and/or defogging. Accordingly, such factors will determine the usage and number of channels **630** as well as the construction, size, shape and configuration of the adapter ring **302** of additional embodiments of the view optimizer **200**.

**[0062]** As shown in FIG. 5A, a laparoscope opening **622** is defined within the inner rim **620** of the adapter ring. The laparoscope opening **622** is adapted to receive the laparoscope **100** and allow for the laparoscope **100** to enter the guard tube **304**. The laparoscope opening **622** may be any size, shape or configuration that allows for the receipt of the laparoscope **100**.

**[0063]** Referring now to FIG. 5B, a rear perspective view of the adapter ring **302** is shown. As shown in FIG. 5B, the laparoscope opening **622** extends through the adapter ring **302**. Also as shown in FIG. 5B, the channels **630** defined within the adapter ring **302** extend to the rear of the adapter ring **302** and open into arcuate shaped openings **640**, **642**, **644** and **646** defined within the rear surface of the adapter ring **302**. As can be seen in FIG. 5B, two of the channels **630** connect with opening **640**, one channel **630** connects with opening **642**, two of the channels **630** connect with opening

**644** and one of the channels **630** connects with opening **646**. In this manner, one pair of the channels **630** are jointly connected to opening **640** and one pair of the channels are jointly connected to opening **644**. Accordingly, the gas and/or liquid traveling through such channels **630** will jointly flow through openings **640** and **644**. Also, any gas and/or liquid which enters openings **640** or **644**, will flow into the pair of channels **630** connected with opening **640** or **644**. Consequently, this allows for one source of gas and/or liquid to be divided into the flow of gas and/or liquid through a pair of channels **630** of the adapter ring and, consequently, a pair of channels **512** of the guard tube **304**.

**[0064]** In the illustrated embodiment of the view optimizer **200**, opening **640** is adapted to receive gas for delivery to the objective lens of the laparoscope **100** through the lens guard **210**, opening **642** is adapted to receive liquid for delivery to the objective lens of the laparoscope **100** through the lens guard **210**, and opening **644** is adapted for the passage of the exhaust gases leaving the patient's body cavity via exhaust vents **516** and passing through the lens guard **210**. In the illustrated embodiment of the view optimizer **200**, opening **646** is not operable to receive the flow of either gas or liquid, however in additional embodiments of the view optimizer **200**, opening **646** may be functional. As mentioned previously, various additional embodiments of the view optimizer **200** may utilize both gas and liquid or one of gas or liquid for delivery to the objective lens of the laparoscope for cleaning and/or defogging. In addition, additional embodiments of the view optimizer may not include a controlled leak function. Accordingly, such factors will affect the construction, size, shape, configuration and functionality of the adapter ring **302**, the channels **630** of the adapter ring **302**, and the openings **640**, **642**, **644**, and **646** of the adapter ring **302** of additional embodiments of the view optimizer **200**.

**[0065]** Referring again to FIG. 3, the view optimizer **200** includes a connection plate **310** that is adapted to abut the adapter ring **302**. The connection plate **310** of the illustrated embodiment is a generally planar, circular disc with a central opening **311** defined through it, and is adapted to permit the laparoscope **100** to pass through the connection plate **310**. The connection plate **310** also has four openings **312** defined through it radially outward from the central opening **311**. The openings **312** are adapted to receive fluid connectors **315**. While the connection plate **310** of the illustrated embodiment has four fluid connectors **315**, additional embodiments of the connection plate **310** may have any number of fluid connectors **315**. The connection plate **310** is adapted to abut against the adapter ring **302** and seal against the openings **640**, **642**, **644** and **646**. Each of the four fluid connectors **315** mounted within the connection plate **310** coincides with one of the openings **640**, **642**, **644** and **646** of the adapter ring **302** described in connection with FIG. 5. Thus, fluid flowing through one of the fluid connectors **315** is free to pass through the connection plate **310** into one of the openings **640**, **642**, **644** and **646** of the adapter ring, through the channels **630** of the adapter ring, through one of the channels **512** of the guard tube, through one of the channels of the exhaust ring and through the end ring **308** for delivery to the objective lens. In addition, exhaust gas that enters the exhaust vents **516** may pass up the guard tube **304**, through the adapter ring **302** and into one of the fluid connectors **315**. Additional embodiments of the view optimizer may not include a connector plate **310** or fluid connectors **315**.

**[0066]** Referring again to FIG. 5B, projecting outwardly from the adapter ring **302** are three fastener portions **650**, each fastener portion **640** having a fastener opening defined there-through. As shown in FIG. 6, the fastener portions **650** are utilized to mount the adapter ring **302** and, consequently, the lens guard **210** to the flow controller **220**. Additional embodiments of the sheath assembly **200** may have any number of fastener portions **650**. The adapter ring **302** of the illustrated embodiment is attached to the flow controller **220** with conventional screws, however, other suitable fasteners, such as adhesives, rivets, tab and slots, etc. could also be used. When the adapter ring **302** and lens guard **210** are mounted to the flow controller **220**, the fluid connectors **315** project into the interior of the flow controller **220**. Also, as mentioned previously, the lens guard **210** and the flow controller **220** may be formed as a one-piece construction in additional embodiments of the view optimizer **200** or may be located remotely from one another and not directly connected to one another. As a result, all embodiments of the view optimizer **200** may not include an adapter ring **302**. It should be understood that additional embodiments of the view optimizer **200** may utilize various methods for mounting the lens guard **210** to the flow controller **220**.

**[0067]** Referring again to FIG. 3, the flow controller **220** will be described with more particularity. The flow controller **220** of the illustrated embodiment of the view optimizer **200** generally includes a base portion **318**, a handle portion **320** and an end cap **330**. The base portion **318**, handle portion **320** and end cap **330** of the illustrated embodiment are adapted to surround and enclose other portions of the view optimizer **200**. The base portion **318**, handle portion **320** and end cap **330** of the illustrated embodiment are molded from plastic, however, other suitable materials can also be used. It should be understood that the base portion **318**, handle portion **320** and end cap **330** of the view optimizer **200** are not limited to the size, shape or configuration set forth in FIG. 3. The base portion **318**, handle portion **320** and end cap **330** of the flow controller **220** of the view optimizer **200** can have any size, shape or configuration that can support and/or enclose other components of the view optimizer **200**.

**[0068]** The base portion **318**, handle portion **320** and end cap **330** are fastened together with a plurality of fasteners **332**. The fasteners **332** of the illustrated embodiment are conventional screws, however, it should be understood that any suitable attachment means could be used. Examples of additional fasteners that can be used include, but are not limited to, any type of screws or bolts, anchors, rivets, cotter pins, clips, snaps, straps, ties, adhesives, weldments, etc. In addition, it should be understood that the flow controller **220** could be formed as one unitary piece in additional embodiments, and need not be provided as multiple pieces that are assembled together.

**[0069]** The base portion **318** of the flow controller **220** has an outer wall **334** that defines an interior cavity **336**. The configuration of the interior cavity **336** of the base portion **318** is adapted to support and enclose other components of the view optimizer **200**. A scope receiver portion **338** extends from the outer wall **334** of the base portion **318** and opens into the interior cavity **336** of the base portion **318**. The scope receiver portion **338** is adapted to receive the laparoscope **100**. The scope receiver portion **338** of the illustrated embodiment of the view optimizer is a cylindrically shaped, threaded channel. However, the scope receiver portion **338** is not limited to this shape or configuration and can have any shape or

configuration that allows it to receive the laparoscope 100. The scope receiver portion 338 of the illustrated embodiment is adapted to receive a grommet 340 that has a cylindrical shape with an opening defined therethrough. The grommet 340 of the illustrated embodiment is rubber, however other suitable materials may also be used, such as plastic or a composite material. The threads of the scope receiver portion 338 are adapted to mate with the threads of a nut 342 which can be tightened onto the scope receiver portion 338. The nut 342 of the illustrated embodiment has an opening defined through it. A second opening (not shown in the figures) is defined within the bottom wall of the base portion 318 of the flow controller 220. This second opening is in communication with the lens guard 210 that is connected to the base portion 318 of the main body (as shown in FIG. 6).

[0070] When the view optimizer 200 is in use, the distal end 120 of the main body 110 of a laparoscope 100 is inserted, in turn, through the opening defined within the nut 342, the opening defined within the grommet 340, and the opening defined within the scope receiver portion 338 by the scope operator. The main body 100 of the laparoscope 100 is then passed through the scope receiver portion 338 and through the base portion 318 of the flow controller 220 into the lens guard 210. Once the distal end 120 of the laparoscope 100 reaches the desired position within the lens guard 210, the nut 342 can be tightened down onto the threads of the scope receiver portion 338. This tightening of the nut 342 forces the grommet 340 to be wedged between the surface of the scope receiver portion 338 and the laparoscope 100, thereby locating the laparoscope in the desired position relative to the flow controller 220 and the lens guard 210, and preventing both linear and rotational movement of the laparoscope relative to the flow controller 220 and the lens guard 210. However, one or both of linear or rotational movement may be allowed in alternative embodiments.

[0071] As illustrated in FIG. 3, the handle portion 320 of the flow controller 220 has a main wall 350 that defines a partially enclosed space. The configuration of the handle portion 320 is adapted to support and enclose other components of the view optimizer 200. The partially enclosed space of the handle portion 320 abuts with the interior cavity 336 of the base portion 318 so the partially enclosed space of the handle portion 320 and the interior cavity 336 of the base portion 318 are in communication when the base portion 318 and the handle portion 320 are joined. Referring to the illustrated embodiment of FIG. 3, a burst actuator compartment 352 and a gas/liquid actuator compartment 354 are defined within the main wall 350 of the handle portion 320. The burst actuator compartment 352 is adapted to hold the burst actuator 360 and the gas/liquid actuator compartment 354 is adapted to hold the gas/liquid actuator/regulator 250. The burst actuator compartment 352 and the gas/liquid actuator compartment 354 of the handle portion 320 are in communication with each other as well as being in communication with the interior cavity 336 of the base portion 318.

[0072] The handle portion 320 of the illustrated embodiment of the view optimizer includes an end cap 330 that is removably attached to the handle portion 320 of the flow controller 220. The end cap 330 is adapted to fully enclose the gas/liquid actuator compartment 354 of the handle portion 320. Additional embodiments of the view optimizer 200 are provided without such an end cap 330. As mentioned previously, additional embodiments of the view optimizer may include a one-piece flow controller 220 as opposed to the

multi-piece flow controller 220 of the illustrated embodiment. The main body can have any shape or configuration that allows it to support and/or enclose other portions of the view optimizer 200.

[0073] The gas inlet 230 and the fluid inlet 240 of the flow controller 220 extend into the gas/liquid actuator compartment 354 of the handle portion 320 of the flow controller 220. The gas inlet 230 and the liquid inlet 240 of the illustrated embodiment of the view optimizer 200 are cylindrical tubes extending outwardly from the surface of the flow controller 220. The gas inlet 230 and liquid inlet 240 are formed from plastic, but a variety of suitable materials could also be used. It should be mentioned that additional shapes and configurations could be used for the gas inlet 230 and liquid inlet 240. The gas inlet 230 and the fluid inlet 240 of the flow controller 220 receive gas and liquid respectively from external sources. The gas inlet 230 and liquid inlet 240 can have any shape or configuration that allows for the connection of the view optimizer 200 to external gas and liquid sources.

[0074] It should be understood that additional embodiments of the view optimizer 200 may include gas and/or liquid sources that are located internally within the view optimizer 200 itself, thus eliminating the need for a means of connecting the view optimizer 200 to external sources of gas and/or liquid. In addition, it should also be understood that additional embodiments of the view optimizer utilize only gas or only liquid. Whether or not the view optimizer 200 utilizes gas, liquid, or both will determine whether a gas or liquid inlet is provided with various additional embodiments of the view optimizer 200.

[0075] The gas/liquid actuator/regulator 250 of the illustrated embodiment of the view optimizer is housed within the gas/liquid actuator compartment 354 of the handle portion 320 of the flow controller 220. The gas/liquid actuator/regulator 250 of the view optimizer 200 can be formed of one of a variety of actuation means. The gas/liquid actuator/regulator 250 of the illustrated embodiment of the view optimizer 200 is a control valve, namely, a manually controlled switching valve. It should be understood, however, that additional embodiments of the view optimizer 200 may include a variety of different types of gas/liquid actuator. Additional embodiments of the view optimizer 200 may include a variety of manually or electrically controlled valves or other device. The gas/liquid actuator/regulator 250 may be any valve or similar device that actuates and/or regulates the flow of the gas and/or liquid utilized by the view optimizer 200 for delivery to the objective lens of the laparoscope 100. The gas/liquid actuator/regulator 250 of the illustrated embodiment is formed from plastic; however, other suitable materials including metals and composites may also be used.

[0076] The gas/liquid actuator/regulator 250 of the embodiment of the view optimizer 200 illustrated in FIG. 3 includes a gas inlet 358, a liquid inlet 360, a gas outlet 362 and a liquid outlet 364. Referring to FIG. 4, the gas inlet 230 of the flow controller 220 is connected to the gas inlet 358 of the gas/liquid actuator/regulator 250 and the liquid inlet 240 is connected to the liquid inlet 360. The embodiment of the gas/liquid actuator/regulator 250 illustrated in FIG. 3 includes an actuation switch 366. The actuation switch 366 of the illustrated embodiment is a push-button that can be selectively operated to actuate the gas/liquid actuator/regulator 250. However, it should be understood that a variety of different switches or other actuation devices can be utilized to perform this function, and the view optimizer 200 of this

application is not limited to a push-button type switch. The actuation switch 366 can be any type of switch or actuation device that can serve to actuate the gas/liquid actuator.

[0077] The gas/liquid actuator/regulator 250 of the illustrated embodiment of the view optimizer 200 is operable to switch between two states, a gas flow state and a liquid flow state. In the gas flow state, gas from an external gas source, such as an insufflator in the case of the illustrated embodiment, flows through the gas inlet 230 of the flow controller 220, through the gas inlet 358 of the gas/liquid actuator/regulator 250, through the gas/liquid actuator/regulator 250 and out the gas outlet 362 of the gas/liquid actuator/regulator 250. When the gas/liquid actuator/regulator 250 is in the gas flow state, liquid is prevented from flowing through the gas/liquid actuator/regulator 250 and out of the liquid outlet 364. Conversely, when the gas/liquid actuator/regulator 250 is in the liquid flow state, liquid from an external source flows through the liquid inlet 240 of the flow controller 220, through the liquid inlet 360 of the gas/liquid actuator/regulator 250, through the gas/liquid actuator/regulator 250 and out the liquid outlet 364 of the gas/liquid actuator/regulator 250. When the gas/liquid actuator/regulator 250 is in the liquid flow state, gas is prevented from flowing through the gas/liquid actuator/regulator 250 and out of the gas outlet 362.

[0078] The gas/liquid actuator/regulator 250 of the illustrated embodiment is biased towards the gas flow state and delivers a generally continuous flow of gas when in the gas flow state. In this manner, the view optimizer 200 of the illustrated embodiment delivers a generally continuous flow of gas to the objective lens of the laparoscope 100 when the gas/liquid actuator/regulator 250 is in the gas flow state. The gas/liquid actuator/regulator 250 of the illustrated embodiment remains in the gas flow state with the view optimizer delivering a generally continuous flow of gas to the objective lens of the laparoscope until an operator switches the gas/liquid actuator/regulator 250 to the liquid flow state by pressing the actuation switch 366 of the gas/liquid actuator/regulator 250. When the gas/liquid actuator/regulator 250 of the illustrated embodiment is switched to the liquid flow state, gas is not permitted to flow through the gas/liquid actuator/regulator 250. The gas/liquid actuator/regulator 250 of the illustrated embodiment only remains in the liquid flow state for as long as the operator is holding the actuation switch 366. Once the operator releases the actuation switch 366, the gas/liquid actuator of the illustrated embodiment returns to the gas flow state. Additional embodiments of the gas actuator/regulator 250 could remain in the liquid flow state until an operator presses on the actuation switch 366. In additional embodiments of the view optimizer, the actuation switch 250 may allow for the flow of both liquid and gas simultaneously. In yet additional embodiments, the gas/liquid actuator/regulator 250 may be biased towards the liquid flow state. Additionally, some view optimizers contemplated by this detailed description may only utilize gas or liquid and the actuation switch 366 of such embodiments will only activate or deactivate the flow of gas or liquid not both and not switch between the flow of gas or liquid. And in still other embodiments, the apparatuses may include more than one actuation switch, each of which independently activates and deactivates the flow of a liquid or a gas, or combinations thereof.

[0079] The burst actuator/regulator 260 of the illustrated embodiment of the view optimizer 200 is housed within the burst actuator compartment 352 of the handle portion 320 of the flow controller 220. The burst actuator/regulator 260 of

the view optimizer 200 can be formed of one of a variety of actuation means. As shown in FIG. 3, the burst actuator/regulator 260 of the embodiment of the view optimizer 200 illustrated in FIG. 3 is a manually operated, pneumatic bulb. However, it should be understood that the burst actuator/regulator 260 can be a variety of different manually or electrically operated devices. The burst actuator/regulator 260 can be any device that allows for the actuation and/or regulation of the burst function of the view optimizer 200. The burst actuator/regulator 260 of the illustrated embodiment is formed from rubber, however other suitable materials may be used. The burst actuator/regulator 260 of the illustrated embodiment has an inlet 370 and an outlet 372. The burst actuator/regulator 260 of the illustrated embodiment is adapted to deliver a burst or bolus of gas and/or liquid to the objective lens of the laparoscope 100 when activated by an operator. It will be understood that in various other embodiments, the apparatuses may include more than one burst actuator, each of which is adapted to work independently to deliver a burst or bolus of a liquid or a gas, or combinations thereof.

[0080] The burst actuator/regulator 260 of the additional embodiments of the view optimizer 200 may be adapted to serve as a gas accumulator (not shown) that accumulate pressurized gas from the insufflator, or from one or more other or additional gas sources. In the event that the insufflator cycles into the static, non insufflating state, the gas within the gas accumulator of such additional embodiments is delivered to the objective lens of the laparoscope via the view optimizer 200. This delivery of gas from the gas accumulator ensures that the view optimizer 200 is supplied with a generally steady supply of gas even when the insufflator cycles into the static state. In this manner, the gas accumulator would act as a damping mechanism to smooth out the cyclic on/off of the insufflator and ensure that a generally steady, continuous flow of gas is delivered to the objective lens of the laparoscope 100.

[0081] As an example, the burst actuator/regulator 260 of some additional embodiments may be an elastic, compliant chamber that expands to accumulate gas from the insufflator. In this manner, the burst actuator/regulator 260 could be used to actuate the delivery of a burst or bolus of gas and or liquid to the objective lens as well as serving as a gas accumulator. A backflow valve may be provided with such burst actuators 260 of additional embodiments to prevent gas from returning to the insufflator from the burst actuator/regulator 260. Such gas accumulators are adapted to accumulate gas from the insufflator until a predetermined, threshold pressure of gas within the gas accumulator is reached. Once the threshold pressure is reached, the gas accumulator would not accumulate any additional gas from the insufflator. This threshold pressure could be maintained within the accumulator either by the use of a valve or similar control mechanism or simply be maintained by the pressure of the flow of gas supplied by the insufflator.

[0082] The gas accumulator of such embodiments is adapted to maintain a pressure that is equal to or greater than the predetermined pressure at which the patient's body cavity is desired to be maintained. Once the pressure within the patient's body cavity drops below the predetermined pressure, due to the cycling off of the insufflator or some other reason, the gas accumulator would deliver gas to the objective lens of the laparoscope 100, thereby, also delivering gas to the patient's body cavity. In instances where an elastic, compliant chamber is supplied as the gas accumulator, the chamber will

elastically contract in response to a pressure differential between the gas accumulator and the patient's body cavity. This contraction of the gas accumulator would serve to deliver gas to the objective lens of the laparoscope 100 and the patient's body cavity. The delivery of gas by such a gas accumulator could be controlled by the utilization of a valve or similar control mechanism. The delivery of such gas could also be delivered in a manner that is not capable of being controlled by the user.

**[0083]** It should be understood that the gas accumulator described above could be provided as a single chamber or multiple chambers. The gas accumulator could be incorporated with the burst actuator/regulator 260 as described above or could be provided separately from the burst actuator/regulator 260. In embodiments in which the burst actuator/regulator 260 and the accumulator function are provided separately from one another, they could each be connected to the insufflator in series or in parallel with respect to one another. Once all or a portion of the gas contained within the gas accumulator has been delivered to the objective lens of the laparoscope, the gas accumulator must be refilled with gas. If the gas accumulator is connected in series with the burst actuator/regulator 260, or other component of the view optimizer 200 that delivers gas to the objective lens, all or a portion of the flow of gas from the insufflator will first fill the gas accumulator to capacity prior to being delivered to the objective lens of the laparoscope. Due to this phenomenon, a decreased amount of flow will be delivered to the objective lens during the filling of the gas accumulator. Upon the initial startup of the insufflator or the cycling of the insufflator to an insufflation state from a static state, this can result in a time period during which little or no gas is delivered to the objective lens of the laparoscope during the filling of the gas accumulator. To prevent this from occurring, in some embodiments of the view optimizer, the gas accumulator is connected to the insufflator in parallel with relation to the burst actuator/regulator 260 or other components of the view optimizer 200 that deliver gas to the objective lens of the laparoscope to ensure that an effective flow of gas to the objective lens is maintained while the gas accumulator is being filled. In such embodiments, a portion of the gas from the insufflator can be diverted to refill the accumulator only if this diverted flow will not cause the flow of gas that is being delivered to the objective lens to drop below an effective amount. In various embodiments, the flow being diverted to the accumulator can be controlled by a valve or other similar control means.

**[0084]** It should be understood that the gas accumulator of additional embodiments could be adapted to accommodate a variety of different volumes of pressurized gas. In yet additional embodiments, the gas accumulator could be a non-compliant chamber that is activated by a control switch or other actuation means to deliver gas to the objective lens of the laparoscope 100 when the insufflator ceases insufflating. Such a gas accumulator could be electronically controlled and connected to the insufflator via electronic circuitry so as to be responsive to the cycling of the insufflator. Finally, it should be understood that additional embodiments of the view optimizer 200 may not be supplied with gas from an insufflator, but, rather, may include a gas supplying device incorporated within the view optimizer 200 that is comparable to the insufflator.

**[0085]** Referring again to FIG. 3, the gas outlet 362 of the gas/liquid actuator/regulator 250 of the illustrated embodiment of the view optimizer 200 is connected to the inlet 370

of the burst actuator/regulator 260. In the embodiment of the view optimizer 200 illustrated in FIG. 4, the gas/liquid actuator/regulator 250 is connected directly to the inlet 370 of the burst actuator/regulator 260. In other embodiments of the view optimizer 200, the gas/liquid actuator/regulator 250 and the burst actuator/regulator 260 are connected indirectly with other intermediate parts being located between them, such as tubing or conduit. In addition, it should be understood that the gas/liquid actuator/regulator 250 and the burst actuator/regulator 260 need not be connected with one another in all embodiments of the view optimizer 200, as they may each receive gas and/or liquid from separate sources. Finally, it should be understood that all embodiments of the view optimizer 200 contemplated by this detailed description do not include both a gas/liquid actuator/regulator 250 and a burst actuator, as additional embodiments may be provided with only a gas/liquid actuator/regulator 250 or burst actuator/regulator 260.

**[0086]** The liquid outlet 364 of the gas/liquid actuator/regulator 250 is connected to one of the fluid connectors 313 of the connection plate by tubing (not shown) that travels through the internal cavity defined within the handle portion 220 and base portion 318 of the flow controller 220. Similarly, the outlet 372 of the burst actuator/regulator 260 is connected to one of the fluid connectors 313 of the connection plate 310 by tubing (not shown) which travels through the internal cavity defined within the handle portion 220 and base portion 318 of the flow controller 220. While tubing is used in some embodiments of the sheath assembly, other suitable methods could be used, such as any type of piping or conduit or flow channels defined within portions of the flow controller 220. The view optimizer of this detailed description is not limited with respect to the method which is used to connect the gas and/or liquid source to the lens guard 210 for delivery to the objective lens of the laparoscope 100.

**[0087]** When the gas/liquid actuator/regulator 250 is in the gas flow state, gas flows from the gas source into the gas inlet 230 of the flow controller 220, through the gas/liquid actuator/regulator 250, through the burst actuator/regulator 260, through a piece or series of tubing into a fluid connector 313 of the connector plate 310, through opening 640 of the adapter ring 302, through a pair of channels 630 of the adapter ring 302, through a pair of corresponding channels 512 of the guard tube 304, through channels 520, 521 of the exhaust ring 306, and is directed across the lens of the laparoscope 100 by passageways 528, 530 of the end ring 308. As mentioned previously, the gas/liquid actuator/regulator 250 of the illustrated embodiment is biased towards the gas flow state and delivers a generally continuous flow of gas from the insufflator when in this state. Accordingly, when the view optimizer 200 of the illustrated embodiment is in the normal operation state, a generally continuous flow of gas is directed across the face of the objective lens of the laparoscope 100 through passageways 528, 530 of the end ring 308. As set forth above, this gas flows in a path that is generally parallel to the objective lens of the laparoscope.

**[0088]** This generally continuous flow of gas across the face of the objective lens of the laparoscope 100 serves to prevent the objective lens from fogging, particularly under circumstances when there is a significant temperature and/or humidity differential between the operating room environment and the body cavity of the patient. The generally continuous flow of gas across the objective lens of the laparoscope also serves to deflect away from the objective lens any

blood, bodily fluids, pieces of tissue, fat or other bodily material that may be encountered by the objective lens of the laparoscope **100** during an operative procedure. If blood, bodily fluids, pieces of tissue, fat or other bodily material is contacted by and sticks to the objective lens of the laparoscope **100**, the gas flow from passageways **528**, **530** serves to remove the material from the objective lens of the laparoscope **100** and to prevent the material from obstructing the view of the surgeon or medical technician through the scope.

**[0089]** The view optimizer **200** of the illustrated embodiment is adapted for use with conventional insufflators that typically provide gas at a flow rate of between zero (0) and fifteen (15) liters per minute when cycling during normal operation. Of course, other insufflators may deliver gas at flow rates that are considerably higher or lower, and may still be useful with the view optimizers disclosed herein. Thus, the view optimizer **200** of this detailed description can be adapted to be used with insufflators having a variety of flow rates. When in the gas flow state during normal operation, the view optimizer **200** of the illustrated embodiment is adapted to divert approximately 9% to 18% of this gas provided from the insufflator for delivery to the objective lens of the laparoscope **100** through the lens guard **210**. Accordingly, the remainder of the gas provided by the insufflator continues to be delivered to the patient's body cavity through one or more of the trocars and not pass through the view optimizer **200**. For example, if the insufflator produces 1 liter per minute (L/min), then 0.1 L/min (10%) would go through the view optimizer **200** to the patient and 0.9 L/min would go through the insufflator trocar to the patient. Additional embodiments of the view optimizer **200** may divert more or less of the flow from the insufflator to the view optimizer **200**. Accordingly, in various embodiments, the view optimizer **200** may divert about 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, or 18% of the gas provided from the insufflator. However it should be understood that additional embodiments of the view optimizer **200** may divert gas from the insufflator in excess of 19, 20, 25, 30, 40, 50, 60, 70, 80, 90% or more. And it will be appreciated that in yet other embodiments, the source of the gas may be from other than the insufflator, in which case there is no diversion of gas from direct delivery to the patient's body cavity.

**[0090]** When in the gas flow state during normal operation, the view optimizer **200** of the illustrated embodiment delivers a generally continuous flow of gas across the objective lens of the laparoscope **100** at a flow rate between zero (0) and ten (10) liters per minute. In some embodiments, the view optimizer **200** delivers a flow of gas at a flow rate between 0.01 and five (5) liters per minute, and in yet other embodiments the view optimizer **200** delivers a flow of gas at a flow rate between two and a half (2.5) and five (5) liters per minute. This generally continuous flow of gas across the objective lens of the laparoscope **100** forms a gas "screen," or "shield." This gas "screen" or "shield" of continuous gas flow across the objective lens of the laparoscope **100** is delivered at a velocity of between zero (0) and about forty (40) meters per second. In some embodiments, the velocity of gas is from about nineteen (19) to thirty eight (38) meters per second. Accordingly, in various embodiments, the flow rate of the gas across the lens is about 0, 0.01, 0.02, 0.03, 0.04, 0.05, 0.06, 0.07, 0.08, 0.09, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 1.7, 1.8, 1.9, 2.0, 2.1, 2.2, 2.3, 2.4, 2.5, 3, 4, 5, 6, 7, 8, 9 or 10 L/min, or increments thereof. And the velocity of the gas screen is about 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, or 25

m/s. However it should be understood that additional embodiments of the view optimizer **200** may deliver gas to the objective lens of the laparoscope at a variety of different flow rates and velocities, in which case such flow rates may exceed 10 L/min or greater and the velocities may exceed 25, 30, 40, 50, 60, 70, 80, 90 or 100 m/s or greater.

**[0091]** During a surgical procedure, blood, bodily fluids, pieces of tissue, fat or other bodily material may become lodged upon the objective lens of the laparoscope and effectively resist deflection or removal by the gas flow provided by the view optimizer in normal operation state. To help facilitate the removal of such adherent material, the view optimizer **200** of the illustrated embodiment provides a burst flow feature. An operator may activate the burst flow feature of the illustrated embodiment of the view optimizer **200** through the use of the burst actuator/regulator **260**. As mentioned previously, the burst actuator/regulator **260** of the illustrated embodiment is a manually operated, pneumatic bulb. To activate the burst flow feature of the illustrated embodiment of the view optimizer **200**, an operator squeezed the pneumatic bulb of the burst actuator/regulator **260**. When the burst actuator/regulator **260** is activated, the view optimizer **200** of the illustrated embodiment delivers a burst or bolus of gas from the insufflator to the objective lens of the laparoscope **100**. During the burst flow state, the view optimizer **200** of the illustrated embodiment delivers a burst or bolus of gas at a flow rate between zero (0) and twenty (20) liters per minute at a velocity of between zero (0) and one hundred and forty five (145) meters per second. Accordingly, in various embodiments, the gas burst flow rate of the gas across the lens is about 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, and 20 L/min, or increments thereof. And the velocity of the gas burst flow is about 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 100, 115, 130, or 145 m/s, or increments thereof. However it should be understood that additional embodiments of the view optimizer **200** may deliver gas burst flow to the objective lens of the laparoscope at a variety of different flow rates and velocities, in which case such flow rates may exceed 20, 25, 30, 35, 40, 45, 50 L/min or greater and such velocities may exceed 150, 155, 160, 165, 170 m/s or greater. The burst or bolus of gas serves to remove blood, bodily fluids, pieces of tissue, fat or other bodily material lodged upon the objective lens of the laparoscope that is resistant to the gas flow provided by the view optimizer in the normal operation state.

**[0092]** As mentioned previously, when the gas/liquid actuator/regulator **250** of the view optimizer **200** of the illustrated embodiment is in the liquid flow state, liquid is delivered to the objective lens of the laparoscope **100** and the delivery of gas ceases. When the gas/liquid actuator/regulator **250** is in the liquid flow state, liquid flows from the liquid source into the liquid inlet **240** of the flow controller **220**, through the gas/liquid actuator/regulator **250**, through a piece or series of tubing into a fluid connector **313** of the connector plate **310**, through opening **642** of the adapter ring **302**, through a channel **630** of the adapter ring **302**, through a corresponding channel **512** of the guard tube **304**, through channel **518** of the exhaust ring **306**, and is directed across the lens of the laparoscope **100** by passageway **526** of the end ring **308**. Accordingly, when the view optimizer **200** of the illustrated embodiment is in the liquid flow state, a generally continuous flow of liquid is directed across the face of the objective lens of the laparoscope **100** through passageway

**526** in a path that is generally parallel to the objective lens. As shown in FIG. 4C, the passageway **526** of the end ring **308** that delivers the fluid to the objective lens is located in a position which directs the flow of the liquid in a path which is generally perpendicular to the flow of the gas provided by channels **528**, **530** of the end ring **308**. However, it should be understood that the view optimizer **200** of the illustrated embodiment is not limited to this configuration of the flow of liquid and gas and additional embodiments of the view optimizer **200** may provide a different configuration of gas and/or liquid flow. In addition, the gas and/or liquid flow of additional embodiments of the view optimizer may be angled towards or away from the objective lens of the laparoscope **100**.

**[0093]** When the gas/liquid actuator is in the liquid flow state, the view optimizer **200** of the illustrated embodiment delivers liquid at a volume of generally between zero (0) and 0.4 liters per minute at a velocity of generally between zero (0) to 0.0075 meters per second. However, it should be understood that additional embodiments of the view optimizer **200** may deliver liquid at various other flow rate and velocities. Accordingly, in various embodiments, the flow rate of the liquid across the lens is about 0, 0.1, 0.2, 0.3, or 0.4 L/min. And the velocity of the liquid flow is about 0 to about 0.0075 m/s. However it should be understood that additional embodiments of the view optimizer **200** may deliver liquid to the objective lens of the laparoscope at a variety of different flow rates and velocities, in which case such flow rates may exceed 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0 or greater and such velocities may exceed 0.0075 m/s or greater. This delivery of liquid to the objective lens of the laparoscope **100** serves to defog or clean the objective lens.

**[0094]** As s the illustrated embodiment of the view optimizer **200** is adapted to deliver a generally continuous flow of gas to the objective lens of the laparoscope **100**, this cycling of the insufflator needs to be prevented. For this reason, the view optimizer **200** of the illustrated embodiment is provided with exhaust vents **516** located within the exhaust ring **306**. When the laparoscope **100** and the view optimizer **200** are inserted into a patient's abdominal cavity during a surgical procedure, the exhaust vents **516** of the exhaust ring **306** are located within the patient's abdominal cavity. Insufflated gas present in the patient's abdominal cavity is able to enter the exhaust vents **516** and travel through a pair of the channels **512** of the guard tube **304**, thus exiting the patient's abdominal cavity. Due to the pressure differential between the interior of the lens guard **210** and the patient's abdominal cavity, this exhaust gas travels through the channels **512** of the guard tube **304**, through a pair of the channels **630** of the adapter ring **302**, through opening **644** of the adapter ring and through one of the fluid connectors **313** located in the connection plate **310**. The fluid connector **313** which the exhaust gas travels through projects into the base portion **318** of the flow controller **220**.

**[0095]** As shown in FIG. 6, an exhaust valve **710** is mounted within the base portion **318** of the flow controller **220**. The fluid connector **313** through which the exhaust gas from within the patient's abdominal cavity passes is connected to the exhaust valve **710** by a piece of or series of tubing (not shown). The exhaust valve **710** can be a variety of different valves or similar devices. The exhaust valve **710** can be any device that can be used to control the flow of the exhaust gases traveling through the view optimizer **200**. The exhaust valve **710** is in communication with exhaust vent **720** defined within the base portion **318** of the flow controller **220**, which is adapted to allow the exhaust gas to exit the view optimizer to the surroundings. The exhaust valve **710** is oper-

able to adjust the flow rate of the exhaust gas exiting the view optimizer **200** via exhaust vent **720**. The controlled leak created by gas entering the lens guard **210** via the exhaust vents **516** and exiting the view optimizer via exhaust vent **720** into the surroundings helps to ensure that the pressure within the patient's abdominal cavity remains below the pre-determined pressure that the insufflator is set to maintain the patient's abdominal cavity. This ensures that the insufflator will continuously insufflate the patient's abdominal cavity and will not shut off during a surgical procedure. Due to the fact that the insufflator is prevented from shutting off, the view optimizer **200** of the illustrated embodiment will be supplied with a generally continuous supply of gas for delivery to the objective lens of the laparoscope. The flow rate of the gas exiting the patients abdominal cavity via exhaust vents **516** can be controlled via exhaust valve **710** to allow for the scope operator to create a desired amount of leakage from the patient's abdominal cavity, while not compromising the effectiveness of the insufflation. As stated previously, however, it should be understood that additional embodiments of the view optimizer **200** may not provide a controlled leak function and, thus, may not include exhaust vents **516**, an exhaust ring **306**, exhaust valve **710** or exhaust valve **720**. In addition, the view optimizer of this detailed description is not limited to the configuration set forth above with respect to the exhaust of gases from within the patients abdominal cavity through the view optimizer, as additional embodiments of the view optimizer may include exhaust systems that are constructed differently.

**[0096]** The illustrated embodiment of the view optimizer **200** is adapted to deliver a generally continuous flow of gas to the objective lens of a laparoscope **100** via end ring **308** of the lens guard **210** for the cleaning and/or defogging of the lens and to deliver a flow of liquid to the objective lens of the laparoscope **100** when the operator desires. It should be understood that additional embodiments of the view optimizer **200** may be adapted to deliver a generally continuous flow of only liquid to the objective lens of the laparoscope **200** or both liquid and gas simultaneously. In addition, additional embodiments of the view optimizer **200** may be adapted to not deliver a continuous flow of gas and/or liquid but, rather, be adapted to only deliver a flow of gas and/or liquid upon the activation of an actuation device.

**[0097]** The illustrated embodiment of the view optimizer **200** is also adapted to deliver a burst or bolus of gas to the objective lens of the laparoscope upon the activation of a burst actuator/regulator **260**. It should be understood that additional embodiments of the view optimizer may be adapted to deliver a burst or bolus of liquid to the objective lens of the laparoscope **200**. It should also be understood that additional embodiments of the view optimizer may be provided without this burst function.

**[0098]** Finally, the illustrated embodiment of the view optimizer **200** is adapted to create a controlled leak of the gases from within the patients abdominal cavity to ensure that the insufflator does not turn off during a surgical procedure or to diminish the frequency of such stoppages of the insufflator. It should be understood that all embodiments of the view optimizer do not include such a controlled leak function. In addition, yet additional embodiments of the view optimizer **200** may create a steady leak, which is not controllable by the operator.

**[0099]** According to some embodiments, vibration of the objective lens of the laparoscope is utilized as an additional means for removing moisture and debris from the objective lens and/or preventing moisture and debris from adhering to the objective lens. According to some such embodiments, the

view optimizer **200** is adapted to utilize the flow of gas from the insufflator to vibrate the objective lens. For example, the end ring **308** is structured in such embodiments in such a way that the flow of gas over or through the end ring **308** vibrates the end ring **308** and, thus, vibrate the objective lens as well. One such embodiment includes an end ring **308** including flexible flaps that are adapted to vibrate the end ring **308** as gas from the insufflator flows over the flaps. Additional embodiments of the view optimizer **200** include mechanical means for vibrating the objective lens that do not utilize the flow of gas from the insufflator. For example, some embodiments utilize a piezoelectric end ring **308** or one or more eccentric weights to vibrate the objective lens. It should be understood that in additional embodiments of the view optimizer **200**, vibration of the objective lens may be provided in combination with one or more of the cleaning and/or defogging methods previously described or may be provided alone.

## EXAMPLES

### Example 1

#### Effect of Venting and Incidence of Scope Removal

**[0100]** Evaluation of effect of venting on insufflator function was evaluated during a laparoscopic surgical procedure. The ambient surgical room temperature was 67°F, the temperature of the carbon dioxide supply was 60 F, and the room humidity was 74%. The following general observations of insufflator function were recorded: after establishing constant pressure in the abdomen sufficient to shut off insufflator operation, followed by a sudden pressure drop in the surgical cavity, there was a 2-3 sec lag before the insufflator restarted. During the standard laparoscopic procedure, the insufflator was in inflation mode~60% of time, and cycled off for a maximum time of about 11 sec.

**[0101]** During a hand assisted laparoscopic procedure, the insufflator was in inflation mode~75% of time, and cycled off for a maximum time of about 5 sec. During the standard laparoscopic procedure, with a slow continuous leak at the stop cock, with the insufflator set at a flow of 5-6 liters per minute and 12-13 mm HG, the insufflator remained in inflation mode 100% of time. During the standard laparoscopic procedure, with a slow continuous leak through a 16G angio-cath, with the insufflator set at a flow of 5 liters per minute and 12-17 mm HG, the insufflator remained in inflation mode 100% of time.

**[0102]** During the standard surgical procedure, without hand assist, the scope was removed from the patient several times, for the reasons and durations as follows: Fog 40 sec; Fog 40 sec; Blood 40 sec; Fog 30 sec; Cautery 25 sec; Cautery 30 sec; Fog 30 sec; and Fog 25 sec. During the standard surgical procedure, with hand assist, the scope was removed from the patient several times, for the reasons and durations as follows: Fog 30 sec; Fog 60 sec; Cautery 25 sec; Cautery 25 sec; Debris 25 sec; Fog 60 sec; Fog 45 sec; Fog 30 sec; and Fog 30 sec.

### Example 2

#### Evaluation of Fogging:

**[0105]** In a device that simulates the humidity and temperature conditions of an animal abdominal cavity during a laparoscopic procedure, the effects of fogging on a laparoscopic lens was evaluated. Chamber temperature of 99.4-99.7° F., and an initial scope lens temperature of 70.1-72.1° F., humidity was 75-77% RH. FIG. 8 shows the change in scope temperature at the lens and various locations along its length at various times at the chambers humidity.

**[0106]** Relative humidity is understood as the Ratio of water vapor (dew point). Above the line corresponding to the relative humidity in the chamber, no condensation is observed; below the line, condensation is observed. The principle was observed in the study, wherein, upon initial insertion of the scope into the chamber, fogging immediately occurred and visualization of an object in the chamber was obscured. It was observed that visualization of the object improved as the scope heated up above dew point temperature, and condensation dissipated.

### Example 3

#### Evaluation of Accumulator Reservoir Function:

**[0109]** Testing was performed in a simulator as described in EXAMPLE 2 to compare insufflator function with and without an accumulator. The conditions of testing were similar for each trial, with chamber temperature of 99.4-99.7° F., and an initial scope lens temperature of 70.1-72.1° F., humidity was 75-77% RH.

**[0110]** The defogging threshold was determined in later testing. A valve was placed inline with an embodiment of the view optimizer described herein and attached to a compliant reservoir. This valve was slowly closed until the airflow was restricted to the point where de-fogging did not occur. Two trials were performed with the chamber temperature being 102.9-103.9° F. with an initial scope lens temperature of 70.5-70.9° F., humidity was 75-76% RH. Observation of the data recorder showed that at steady state, the maximum peak flow was registered at 1.3V during this time. The voltage of the sensor at 0 flow was measured pretest at 1.228V. FIG. 9 shows the resulting data, wherein the use of an accumulator reservoir compensated for the insufflator to deliver a continuous stream of air when the insufflator was shut-off, and a shift in flow was observed upon re-initiation of insufflator function until the compliant reservoir was replenished with gas.

**[0111]** The embodiments and examples of the view optimizer **200** described herein are representative of aspects of the invention and are provided as examples and not an exhaustive description of implementations of an aspect of the invention. While various aspects of the view optimizer **200** are described and illustrated herein as embodied in combination in the exemplary embodiments, these various aspects may be realized in many alternative embodiments, either individually or in various combinations and sub-combinations thereof. Unless expressly excluded herein all such combinations and sub-combinations are intended to be within the scope of the present application. Still further, while various alternative embodiments as to the various aspects and features of the invention, such as alternative materials, structures, configurations, methods, devices, such descriptions are not intended to be a complete or exhaustive list of available alternative embodiments, whether presently known or later developed. Those skilled in the art may readily adopt one or more of the aspects, concepts or features of the invention into additional embodiments within the scope of the present invention even if such embodiments are not expressly disclosed herein. Additionally, even though some features, concepts or aspects of the invention may be described herein as being a preferred arrangement or method, such description is not intended to suggest that such feature is required or necessary unless expressly so stated.

1. A view optimizer for use with a surgical scope, comprising:

- a lens guard having at least a first passageway that has a proximal end and a distal end, the proximal end of the passageway connected to a source of gas, the distal end oriented to deliver gas to an outer surface of an objective

lens of the surgical scope when the view optimizer is assembled with the surgical scope, the lens guard adapted to deliver a stream of gas to the outer surface of the objective lens at an essentially continuous rate of 0.07 liters per minute to 10 liters per minute, and at an average velocity from 0.01 to 30 meters per second.

2. The view optimizer of claim 1, the lens guard adapted to deliver a stream of gas at an essentially continuous rate of 0.1 liters per minute to 5 liters per minute.

3. The view optimizer of claim 1, the lens guard adapted to deliver a stream of gas at an essentially continuous rate of 0.07 liters per minute to 0.5 liters per minute.

4. The view optimizer of claim 1, comprising a valve connected with the first passageway, the valve being movable between at least a first position, in which flow through the first passageway is permitted, and a second position, in which flow through the first passageway is blocked.

5. The view optimizer of claim 1, comprising an actuator connected with the first passageway, the actuator being selectively activated, wherein the view optimizer is adapted to deliver gas to an outer surface of the objective lens at a first flow rate when the actuator is not activated and a second flow rate when the actuator is activated, the second flow rate being greater than the first flow rate.

6. The view optimizer of claim 1, further comprising a second passageway, at least a portion of the second passageway defined within the lens guard, the second passageway having a proximal end and a distal end, the proximal end connected to a source of liquid, the distal end being oriented to deliver liquid to an outer surface of the lens when the view optimizer is assembled with the surgical scope,

wherein the liquid is delivered to the outer surface of the objective lens at an essentially continuous rate from 0.01 to 0.4 liters per minute and at a velocity from 0.0005 to 0.0075 meters per second.

7. The view optimizer of claim 6, comprising a valve connected with the second passageway, the valve being movable between at least a first position, in which flow through the second passageway is permitted, and a second position, in which flow through the second passageway is blocked.

8. The view optimizer of claim 6, comprising an actuator connected with the second passageway, the actuator being selectively activated, wherein the view optimizer is adapted to deliver liquid to an outer surface of the objective lens at a first flow rate when the actuator is not activated and a second flow rate when the actuator is activated, the second flow rate being greater than the first flow rate.

9. The view optimizer of claim 7, wherein when the valve is in the first position, flow through the first passageway is permitted and flow through the second passageway is blocked, and when the valve is in the second position, flow through the second passageway is permitted and flow through the first passageway is blocked.

10. The view optimizer of claim 1, comprising a valve connected with the first passageway, and wherein the first passageway is connected at its proximal end with a source of liquid, the valve being movable between at least a first position and a second position, wherein when the valve is in the first position, flow of gas at an essentially continuous rate through the first passageway is permitted, and when the valve is in the second position, flow of liquid at an essentially continuous rate through the first passageway is permitted.

11. The view optimizer of claim 5, wherein the actuator defines a portion of the first passageway, such that flow through the first passageway passes through the actuator.

12. The view optimizer of claim 1, wherein the lens guard is configured to at least partially surround a portion of the surgical scope.

13. The view optimizer of claim 1 wherein the objective lens has a central axis and the lens guard is configured to extend between generally between 0 millimeters and 7 millimeters beyond the outer surface of the objective lens in an axial direction.

14. The view optimizer of claim 1, wherein the lens guard further comprises an exhaust passageway having a distal end including at least one vent that is open to an outer surface of the lens guard, and a proximal end connected to an exhaust valve movable between open and closed positions; wherein when the view optimizer is inserted into a body cavity and the valve is in the open position, gas surrounding the distal end of the exhaust passageway is permitted to enter the exhaust passageway through the at least one vent and exit the body cavity through the exhaust passageway.

15. A view optimizer for use with a surgical scope, the view optimizer supplied with gas from an insufflator, the insufflator adapted to insufflate a body cavity to a predetermined pressure, the insufflator adapted to cycle between and insufflating state when the pressure within the body cavity is below the predetermined pressure and a static state when the pressure within the body cavity is equal to or greater than the predetermined pressure, the view optimizer comprising:

a lens guard;

a first passageway, at least a portion of the first passageway defined within the lens guard, the first passageway having a proximal end and a distal end, the proximal end connected to a source of gas, the distal end oriented to deliver gas to an outer surface of an objective lens of the surgical scope when the view optimizer is assembled with the surgical scope; and

an exhaust passageway, at least a portion of the exhaust passageway defined within the lens guard, the exhaust passageway having a distal end including at least one vent that is open to an outer surface of the lens guard, and a proximal end connected to an exhaust valve movable between open and closed positions; wherein when the view optimizer is inserted into a body cavity and the valve is in the open position, gas surrounding the distal end of the exhaust passageway is permitted to enter the exhaust passageway through the at least one vent and exit the body cavity through the exhaust passageway, wherein the gas exiting the body cavity through the exhaust passageway prevents the pressure within the body cavity from equaling or exceeding the predetermined pressure and thereby prevents the insufflator from cycling to the static state.

16. The view optimizer of claim 15, wherein at least a portion of a second passageway having a proximal end and a distal end is defined within the lens guard, the proximal end being connected to a source of liquid, the distal end being oriented to deliver the liquid to an outer surface of the objective lens when the view optimizer is assembled with the surgical scope.

17. The view optimizer of claim 16, further comprising a valve connected with the first and second passageways, the valve being movable between a first position, in which flow through the first passageway is permitted and flow through

the second passageway is blocked, and a second position, in which flow through the first passageway is blocked and flow through the second passageway is permitted.

**18.** The view optimizer of claim **16**, wherein the lens guard comprises an outer cylindrical wall, an inner cylindrical wall sized to surround a portion of the surgical scope, and a plurality of dividing walls extending radially from the inner cylindrical wall to the outer cylindrical wall to define portions of the first passageway, the second passageway, and the exhaust passageway.

**19.** The view optimizer of claim **15**, further comprising an end ring assembled to the distal end of the lens guard, the end ring comprising first and second inner recesses that align with the first and second passageways to direct the flow of fluid from the first and second passageways across the outer surface of the objective lens when the view optimizer is assembled with the surgical scope.

**20.** The view optimizer of claim **15**, further comprising an actuator connected with the first passageway, the actuator being selectively activated to deliver a burst of gas through the first passageway and across the lens.

**21.** A view optimizer for a surgical scope, the view optimizer being supplied with gas from an insufflator, the insufflator being adapted to insufflate a body cavity to a predetermined pressure, the insufflator being adapted to cycle between and insufflating state when the pressure within the body cavity is below the predetermined pressure and a static state when the pressure within the body cavity is equal to or greater than the predetermined pressure, the view optimizer comprising:

an exhaust passageway having a distal end including at least one vent that is open to an outer surface of the view optimizer, and a proximal end; wherein when the view optimizer is inserted into a body cavity gas surrounding the distal end of the exhaust passageway is permitted to enter the exhaust passageway through the at least one vent and exit the body cavity through the exhaust passageway, wherein the gas exiting the body cavity through the exhaust passageway prevents the pressure within the body cavity from equaling or exceeding the predetermined pressure and thereby prevents the insufflator from cycling to the static state.

**22.** A view optimizer for use with a surgical scope, the view optimizer comprising:

a main housing;  
a lens guard connected to the main housing;  
at least one gas delivery passageway defined within the lens guard that is adapted to deliver gas to an outer surface of an objective lens of the surgical scope when the view optimizer is assembled with the surgical scope;  
at least one liquid delivery passageway defined within the lens guard that is adapted to deliver liquid to an outer surface of the lens when the view optimizer is assembled with the surgical scope;  
at least one actuator connected with at least one gas delivery passageway or the at least one liquid delivery passageway, the at least one actuator being selectively activated, wherein the view optimizer is adapted to deliver at least one of gas or liquid to an outer surface of the objective lens at a first flow rate when the at least one

actuator is not activated and a second flow rate when the at least one actuator is activated, the second flow rate being greater than the first flow rate; and

at least one exhaust passageway defined within the lens guard, wherein when the view optimizer is inserted into a body cavity, the at least one exhaust passageway is adapted to permit gas to enter the at least one exhaust passageway and exit the body cavity through the exhaust passageway.

**23.** The view optimizer of claim **22**, the view optimizer being supplied with gas from an insufflator, the insufflator being adapted to insufflate a body cavity to a predetermined pressure, the insufflator being adapted to cycle between and insufflating state when the pressure within the body cavity is below the predetermined pressure and a static state when the pressure within the body cavity is equal to or greater than the predetermined pressure, the view optimizer further comprising:

a gas accumulator, the gas accumulator being adapted to store a portion of the gas supplied from the insufflator, the gas accumulator being further adapted to deliver gas stored within the gas accumulator to the first passageway for delivery to an outer surface of the objective lens of the surgical scope when the insufflator is in the static state.

**24.** The view optimizer of claim **22**, comprising a valve connected with the with at least one gas delivery passageway or the at least one liquid delivery passageway, the valve being movable between at least a first position, in which flow through the at least one gas delivery passageway is permitted and flow through the at least one liquid delivery passageway is blocked, and a second position, in which flow through the at least one liquid delivery passageway is permitted and flow through the at least one gas delivery passageway is blocked.

**25.** The view optimizer of claim **22** wherein the lens guard is adapted to deliver a stream of gas to the outer surface of the objective lens at an essentially continuous rate of 0.07 liters per minute to 10 liters per minute, and at an average velocity from 0.01 to 30 meters per second.

**26.** The view optimizer of claim **22** wherein the lens guard is adapted to deliver a stream of liquid to the outer surface of the objective lens at an essentially continuous rate from 0.01 to 0.4 liters per minute and at a velocity from 0.0005 to 0.0075 meters per second.

**27.** The view optimizer of claim **24** wherein when the valve is in the first position, flow of gas at an essentially continuous rate from 0.1 to 2.5 liters per minute and at a velocity from 0.1 to 19 meters per second through the at least one gas delivery passageway is permitted, and when the valve is in the second position, flow of liquid at an essentially continuous rate from 0.01 to 0.4 liters per minute and at a velocity from 0.0005 to 0.0075 meters per second through the at least one liquid delivery passageway is permitted.

**28.** The view optimizer of claim **22** wherein the objective lens has a central axis and the lens guard is configured to extend between generally 0 millimeters and 7 millimeters beyond the outer surface of the objective lens in an axial direction.
