EP 1 416 965 B1

DescriptionTechnical Field

5 **[0001]** The invention relates to an assay which permits diagnosis of preclinical and clinical Alzheimer's disease. The test relies on assessing the levels of amyloid beta (A β) peptide in plasma following administration of certain anti-A β antibodies to a subject.

Background Art

10 **[0002]** A number of symptomologies which result in cognitive deficits, stroke, brain hemorrhage, and general mental debilitation appear to be associated with neuritic and cerebrovascular plaques in the brain containing the amyloid beta peptide (A β).

15 Among these conditions are both preclinical and clinical Alzheimer's disease, Down's syndrome, and preclinical and clinical cerebral amyloid angiopathy (CAA). The amyloid plaques are formed from amyloid beta peptides. These peptides circulate in the blood and in the cerebrospinal fluid (CSF). The A β peptide in circulating form is composed of 39-43 amino acids (mostly 40 or 42 amino acids) resulting from the cleavage of a common precursor protein, amyloid precursor protein, often designated APP.

20 **[0003]** Evidence suggests that A β can be transported back and forth between brain and the blood (Ghersi-Egea, J-F., et al., J. Neurochem. (1996) 67:880-883; Zlokovic, B.V., et al., Biochem. Biophys. Res. Comm. (1993) 67:1034-1040; Shibata, M., et al., J. Clin. Invest. (2000)106:1489-1499. Further A β in plaques is in an equilibrium with soluble A β in the brain and blood (Kawarabayashi, T., et al., J Neurosci. (2001) 21:372-381), DeMattos et al., Proc. Nat'l.Acad Sci USA (2001) 98:8850-8855.

25 **[0004]** As described in WO01/4987, total circulating levels of A β peptide in CSF are similar in normal individuals and individuals predisposed to exhibit the symptoms of Alzheimer's. However, A β_{42} levels are lower on average in individuals with Alzheimer's disease (Nitsch, R.M., et al., Ann. Neurol. (1995) 37:512-518). It is known that A β_{42} is more prone to aggregate than is A β_{40} , and when this happens, adverse consequences such as A β deposition in amyloid plaques, conversion of A β to toxic forms, nerve cell damage, and behavioral impairment such as dementia ensue (Golde, T.E., et al., Biochem. Biophys. Acta. (2000) 1502:172-187).

30 **[0005]** WO01/62801 entitled "Humanized Antibodies That Sequester A β Peptide" filed 26 February 2001 describes antibodies which do not appreciably cross the blood-brain barrier and which sequester A β peptides circulating in biological fluids. These antibodies are described as useful for preventive and therapeutic treatment of conditions associated with the formation of A β -containing diffuse, neuritic, and cerebrovascular plaques in the brain. The application describes administering the antibodies and then measuring circulating levels of A β peptide in blood in order to assess the progress of therapy. There is no clear suggestion, however, that the levels of A β peptide following administration of the antibodies are diagnostic of the condition itself. The present invention resides in the surprising result that enhanced levels of both A β_{40} and A β_{42} as well as the A β_{40} /A β_{42} ratio correlate with the levels of A β peptide deposition in the brain when the antibodies have been administered to an individual. Thus, measurement of these components in the blood after administration of the antibody provides a simple straightforward diagnostic test for both clinical and preclinical Alzheimer's disease and related neurological disorders.

35 **[0006]** There are additional relevant publications concerning the behaviour of A β peptide antibodies. For example, PCT publication W099/27944 published 10 June 1999 describes methods to induce an immune response in order to reduce amyloid deposits. Publication No. W099/60024 published 25 November 1999, describes methods for amyloid removal using anti-amyloid antibodies. Additional PCT publications, including WO00/72880, WO00/72876 and WO00/77178 all describe various activities of anti-A β peptide antibodies. Antibodies directed to the N-terminus of this peptide are said to reduce plaques in a transgenic murine model; immunization with the amyloid itself is described as are antibodies designed to catalyze hydrolysis of the peptide.

40 **[0007]** It has been shown that one pathway for A β metabolism is via transport from CNS to the plasma (Zlokovic, B.V., et al., Proc. Natl. Acad. Sci (USA) (1996) 93:4229-4234; Ghersi-Egea, J-F., et al., J. Neurochem.(1996)67:880-883). Additionally, it has been shown that A β in plasma can cross the blood-brain-barrier and enter the brain (Zlokovic, B.V., et al., Biochem. Biophys. Res. Comm. (1993) 67:1034-1040). It has also been shown that administration of certain polyclonal and monoclonal A β antibodies decreases A β deposition in amyloid plaques in the APP^{V717F} transgenic mouse model of Alzheimer's disease (Bard, F., et al., Nature Med. (2000) 6:916-919). This was said to be due to certain anti-A β antibodies crossing the blood-brain-barrier and stimulating phagocytosis of amyloid plaques by microglial cells. In Bard's experiments, assays of brain slices *ex vivo* showed that the presence of added A β antibody, along with exogenously added microglia, induced phagocytosis of A β , resulting in removal of A β deposits.

45 **[0008]** The levels of both soluble A β_{40} and A β_{42} in CSF and blood can readily be detected using standardized assays using antibodies directed against epitopes along the A β chain. Such assays have been reported, for example, in U.S.

patents 5,766,846; 5,837,672; and 5,593,846. These patents describe the production of murine monoclonal antibodies to the central domain of the A β peptide, and these were reported to have epitopes around and including positions 16 and 17. Antibodies directed against the N-terminal region were described as well. Several monoclonal antibodies were asserted to immunoreact with positions 13-28 of the A β peptide; these did not bind to a peptide representing positions 17-28, thus, according to the cited patents, establishing that it is this region, including positions 16-17 (the 0-secretase site) that was the target of these antibodies. Among antibodies known to bind between amino acids 13 and 28 of A β are mouse antibodies 266 (m266), 4G8, and 1C2.

Disclosure of the Invention

[0009] It has now been found that antibodies which are useful for performing assays for A β peptide, and which are useful in treatment of conditions associated with amyloid plaques in the brain can elicit a response which results in a marked increase in the level of A β peptide in the blood and this level can be used as a diagnostic marker for clinical and preclinical Alzheimer's disease. These antibodies, which may or may not be humanized, sequester A β peptide from its bound, circulating form in blood and alter clearance of soluble and bound forms of A β in central nervous system and plasma. These antibodies, and fragments thereof, specifically bind to an epitope between amino acids 13 and 28 of the A β molecule. The CDR of these antibodies can be derived from mouse monoclonal antibody 266 (SEQ ID NO: 1 through SEQ ID NO:6). Useful antibodies include antibodies and fragments thereof, wherein the variable regions have sequences comprising the CDR from mouse antibody 266 and specific human framework sequences (SEQ ID NO:7 through SEQ ID NO:10), wherein the antibodies retain approximately the binding properties of the mouse antibody and have *in vitro* and *in vivo* properties functionally equivalent to the mouse antibody 266. Especially useful are humanized antibodies and fragments thereof, wherein the light chain is SEQ ID NO:11 and the heavy chain is SEQ ID NO:12.

[0010] Thus in one aspect, the invention is directed to a method of diagnosing preclinical or clinical Alzheimer's disease comprising:

(a) measuring one or more of

- (i) the level of A β_{40} ;
- (ii) the level of A β_{42} ; or
- (ii) the ratio A β_{40} /A β_{42} ;

in a blood sample of a subject obtained at a time interval after administering to said subject an amount of an antibody which specifically binds an epitope contained within positions 13-28 of A β or an antibody that sequesters A β peptide from its bound, circulating form in the blood and alters clearance of soluble and bound forms of A β in the central nervous system in plasma, wherein said amount is effective to alter the levels of circulating A β peptides in the blood of said subject when said subject is in a preclinical or clinical stage of Alzheimer's disease; and

(b) comparing the level of A β_{40} , A β_{42} , or the ratio of A β_{40} /A β_{42} in said subject with a control value of said levels, wherein elevated levels of A β_{40} , A β_{42} , or the ratio of A β_{40} /A β_{42} in said subject as compared to control levels or ratio identifies said subject as in a preclinical or clinical stage of Alzheimer's disease.

Brief Description of the Drawings

[0011]

Figures 1 A, B and C are graphs showing the levels of A β_{40} (Figure 1A), A β_{42} (Figure 1B), and A β_{40} /A β_{42} ratio (Figure 1C) in plasma of transgenic mice prior to administration of the antibody m266, and the lack of correlation with brain A β deposits.

Figures 2 A and B are graphs showing plasma A β_{40} (Figure 2A) and plasma A β_{40} /A β_{42} ratio (Figure 2B) in transgenic mice one hour after injection of antibody m266, and the significant correlation with brain A β deposits.

Figures 3 A, B and C are graphs showing the significant correlations of the two A β peptides (Figures 3A and 3B) and their ratio (Figure 3C) with A β peptide deposition in the brain 24 hours after injection with monoclonal antibody m266.

Figures 4 A, B and C are graphs showing the significant correlations of entry rates into the circulation of the two A β peptides (Figures 4A and 4B) and their ratio (Figure 4C) and A β peptide deposition in transgenic mice.

Figures 5 A and B are graphs showing an alternative graphical representation of A β ₄₀ levels in the plasma 24 hours (Figure 5A) and 1 hour (Figure 5B) after m266 injection correlated with the percentage hippocampus covered by A β deposits.

5 Figure 6 is a table showing Pearson correlation coefficients (Pearson *r*) and significance (P value) determined between plasma A β values (pre and post injection of m266) and hippocampal A β or amyloid load.

Modes of Carrying Out the Invention

10 **[0012]** The A β peptides that circulate in human biological fluids represent a carboxy terminal region of a precursor protein encoded on chromosome 21. It has been reported from the results of *in vitro* experiments that the A β peptide has poor solubility in physiological solutions, since it contains a stretch of hydrophobic amino acids which are a part of the region that anchors its longer precursor to the lipid membranes of cells. It is thus not surprising that circulating A β peptide is normally complexed with other moieties that prevent it from aggregating. This has resulted in difficulties in
15 detecting circulating A β peptide in biological fluids.

[0013] The above-mentioned patent documents (U.S. patents 5,766,846; 5,837,672 and 5,593,846) describe the preparation of antibodies, including a monoclonal antibody, designated clone 266 (m266), which was raised against, and has been shown to bind specifically to, a peptide comprising amino acids 13-28 of the A β peptide. Applicants have found that after administering m266 to APP^{V717F} mice, a mouse model of Alzheimer's disease, they can measure levels
20 of A β peptides in the circulation that are diagnostic of the levels of amyloid plaques in the brain. Thus, these antibodies are useful not only in conducting assays for circulating A β peptides *per se*, but also for eliciting circulating blood levels which are diagnostic of the amount of amyloid plaque in the brain, and thus useful in identifying individuals in clinical and preclinical stages of Alzheimer's disease. One such antibody, m266, bonds to the mid-region of A β peptide.

[0014] By "monoclonal antibody that bonds to the mid-region of A β peptide" is meant a monoclonal antibody (Mab or Mabs) that binds an amino acid sequence representing an epitope contained between positions 13-28 of A β . The entire region need not be targeted. As long as the antibody binds at least an epitope within this region (especially, *e.g.*, including the α -secretase site 16-17 or the site-at which antibody 266 binds), such antibodies are effective in the method of the invention.

[0015] By "antibody" is meant a monoclonal antibody *per se*, or an immunologically effective fragment thereof, such, as an F_{ab}, F_{ab'}, or F_{(ab')₂} fragment thereof. In some contexts, herein, fragments will be mentioned specifically for emphasis; nevertheless, it will be understood that regardless of whether fragments are specified, the term "antibody" includes such fragments as well as single-chain forms. As long as the protein retains the ability specifically to bind its intended target, and in this case, to sequester A β peptide from its carrier proteins in blood, it is included within the term "antibody." Also included within the definition "antibody" for example, are single chain forms, generally designated F_v, regions, of antibodies
35 with this specificity. Preferably, but not necessarily, the antibodies useful in the invention are produced recombinantly, as manipulation of the typically murine or other non-human antibodies with the appropriate specificity is required in order to convert them to humanized form. Antibodies may or may not be glycosylated, though glycosylated antibodies are preferred. Antibodies are properly cross-linked via disulfide bonds, as is well-known.

[0016] The basic antibody structural unit is known to comprise a tetramer. Each tetramer is composed of two identical pairs of polypeptide chains, each pair having one "light" (about 25 kDa) and one "heavy" chain (about 50-70 kDa). The amino-terminal portion of each chain includes a variable region of about 100 to 110 or more amino acids primarily responsible for antigen recognition. The carboxy-terminal portion of each chain defines a constant region primarily responsible for effector function.

[0017] Light chains are classified as gamma, mu, alpha, and lambda. Heavy chains are classified as gamma, mu, alpha, delta, or epsilon, and define the antibody's isotype as IgG, IgM, IgA, IgD and IgE, respectively. Within light and heavy chains, the variable and constant regions are joined by a "J" region of about 12 or more amino acids, with the heavy chain also including a "D" region of about 10 more amino acids.

[0018] The variable regions of each light/heavy chain pair form the antibody binding site. Thus, an intact antibody has two binding sites. The chains all exhibit the same general structure of relatively conserved framework regions (FR) joined
50 by three hypervariable regions, also called complementarily determining regions or CDRs. The CDRs from the two chains of each pair are aligned by the framework regions, enabling binding to a specific epitope. From N-terminal to C-terminal, both light and heavy chains comprise the domains FR1, CDR1, FR2, CDR2, FR3, CDR3 and FR4. The assignment of amino acids to each domain is in accordance with well known conventions [Kabat "Sequences of Proteins of Immunological Interest" National Institutes of Health, Bethesda, Md., 1987 and 1991; Chothia, et al., J. Mol. Bio. (1987) 196:901-917; Chothia, et al., Nature (1989) 342:878-883].

[0019] As is well understood in the art, monoclonal antibodies can readily be generated with appropriate specificity by standard techniques of immunization of mammals, forming hybridomas from the antibody-producing cells of said mammals or otherwise immortalizing them, and culturing the hybridomas or immortalized cells to assess them for the

[0031] Other sequences are possible for the light and heavy chains for the humanized antibodies and for humanized 266. The immunoglobulins can have two pairs of light chain/heavy chain complexes, at least one chain comprising one or more mouse complementarity determining regions functionally joined to human framework region segments.

[0032] Starting at position 56 of the heavy chain variable region, both m266 and humanized 266 contain the sequence Asn-Ser-Thr. This sequence is an example of the Asn-X-Ser/Thr signal for N-linked glycosylation, wherein the Asn is the site of attachment of N-linked glycosyl chains. Both m266 and humanized 266 are extensively glycosylated at this site. Quite unpredictably and advantageously, the affinity of humanized 266 that is deglycosylated in the heavy chain CDR2 for A β peptide is markedly higher than that of humanized 266. The heavy chain CDR2 of deglycosylated humanized 266 has the following amino acid sequences:

heavy chain CDR2:

20% by weight and will be selected primarily based on fluid volumes, viscosities, and so forth, in accordance with the particular mode of administration selected. Thus, a typical composition for injection could be made up to contain 1 mL sterile buffered water of phosphate buffered saline and 1-1000 mg, preferably 10-100 mg, of the humanized antibody. The formulation could be sterile filtered after making the formulation, or otherwise made microbiologically acceptable.

A typical composition for intravenous infusion could have volumes between 1-250 mL of fluid, such as sterile Ringer's solution, and 1-100 mg per mL, or more in antibody concentration. Therapeutic agents can be frozen or lyophilized for storage and reconstituted in a suitable sterile carrier prior to use. Lyophilization and reconstitution can lead to varying degrees of antibody activity loss (e.g. with conventional immune globulins, IgM antibodies tend to have greater activity loss than IgG antibodies). Dosages may have to be adjusted to compensate. The pH of the formulation will be selected to balance antibody stability (chemical and physical) and comfort to the patient when administered. Generally, pH between 4 and 8 is tolerated.

[0045] Although the foregoing methods appear the most convenient and most appropriate for administration of proteins such as humanized antibodies, by suitable adaptation, other techniques for administration, such as transdermal administration and oral administration may be employed provided proper formulation is designed.

[0046] In addition, it may be desirable to employ controlled release formulations using biodegradable films and matrices, or osmotic mini-pumps, or delivery systems based on dextran beads, alginate, or collagen.

[0047] In summary, formulations are available for administering the antibodies and are well-known in the art and may be chosen from a variety of options.

[0048] Typical dosage levels can be optimized using standard clinical techniques and will be dependent on the mode of administration.

[0049] After administration of the antibody to the subject, blood samples are withdrawn at periodic intervals over the succeeding minutes, hours, or days. Suitable time periods may be as short as a few minutes, 10 minutes, 30 minutes, or 1 hour, several hours, or days may be allowed to elapse before withdrawal of the blood sample. Measurement after less than 3 hours is preferred. If desired, the plasma fraction can be obtained for ease of analysis. Standard analytic techniques for analysis of the $A\beta_{40}$, $A\beta_{42}$ and the ratio thereof are used. These techniques are described, for example, in U.S. patent 5,766,846. Any suitable technique for analysis, however, can be employed, such as chromatographic separation, Western blotting, ELISA assays, homogenous assays and the like.

[0050] The concentration of the $A\beta_{40}$, $A\beta_{42}$, or their ratio is then compared to these values in a control. Typical controls include individuals known to be free of conditions associated with the amyloid plaques, such as teenagers or very young adults and in addition, age-matched cognitively normal controls are obtained by averaging values from the general population. While some elderly age-matched cognitively normal controls have pre-clinical AD, most do not. Thus, the average values from such a population will be useful and critical to obtain. Design of standard controls is a process that is well known to the ordinary practitioner. Individuals who have elevated levels of the stated peptides or of the ratio of $A\beta_{40}$ to $A\beta_{42}$ as compared to the control values are then identified as having a high likelihood of clinical or preclinical conditions associated with the formation of amyloid plaques.

[0051] The following examples are intended to illustrate but not to limit the invention.

[0052] The examples hereinbelow employ, among others, a murine monoclonal antibody designated "266" which was originally prepared by immunization with a peptide comprised of residues 13-28 of human $A\beta$ peptide. The antibody was confirmed to immunoreact with this peptide, but had previously been reported to not react with the peptide containing only residues 17-28 of human $A\beta$ peptide, or at any other epitopes within the $A\beta$ peptide. The preparation of this antibody is described in U.S. patent 5,766,846. As the examples here describe experiments conducted in murine systems, the use of murine monoclonal antibodies is satisfactory. However, humanized forms of the antibodies with the immunospecificity corresponding to that of antibody 266 are preferred.

Example 1

Correlation of Circulating Peptide Levels with Plaques

[0053] A murine model for Alzheimer's disease, APP V717F transgenic mice, was used in this assay. These mice are described by Games, D., et al., Nature (1995) 373:523-527; Bales, K.R., et al., Nature Genet. (1997) 17:263-264; and by Holtzman, D.M., et al., Proc. Natl. Acad. Sci. U.S.A. (2000) 97:2892-2897. In this model, a mutant form of the human APP gene is expressed and results in an early onset form of familial Alzheimer's disease. Although the brains of these mice appear normal initially, $A\beta$ deposition in the form of diffuse and neuritic plaques occurs at 6-15 months, although mice homozygous for the transgene show variability in that at 9-14 months of age, some mice develop $A\beta$ deposits while others do not.

[0054] 53 homozygous mice at 12 months were used in this study.

[0055] Plasma levels of $A\beta_{40}$, $A\beta_{42}$, and $A\beta_{40}/A\beta_{42}$ ratios were measured by ELISA in the plasma of these mice prior to administration of 500 μ g of m266 and at various time intervals up to 24 hours after administering this antibody. After

24 hours, the mice were sacrificed, and the amount of A β deposition in the brain was assessed in the hippocampus and cortex as described by DeMattos, et al. Proc. Nat'l. Acad. Sci USA (2001) 98:8850-8855, and evaluated as a percentage of brain covered by A β deposits.

5 [0056] As shown in Figures 1 A, B and C, if the percentage A β coverage due to deposition in the hippocampus is plotted on the x-axis against the levels of the peptides and their ratio in plasma on the y-axis prior to administration of the antibody, no correlation is found. Regardless of whether the percent A β deposition was essentially zero (0) or over 75%, the average level of A β_{40} was approximately 250 (pg/ml) and of A β_{42} approximately 400 (pg/ml). The ratio of A β_{40} to A β_{42} was thus approximately 0.5-0.6.

10 [0057] As shown in Figures 2 A and B, however, the plasma level of A β_{40} strongly correlated with the percentage of A β deposition in hippocampus one hour after m266 injection, as did the ratio of A β_{40} to A β_{42} .

[0058] Figures 3 A, B and C show similar results obtained 24 hours post injection. The levels obtained of A β_{40} and the A β_{40} /A β_{42} ratio strongly correlated with the % A β deposition in hippocampus. The A β_{42} levels also correlated with % A β deposition but not as well as A β_{40} levels.

15 [0059] Figures 4 A, B and C show analogous results with respect to entry rate of the two A β peptides into the plasma and the calculated values for the entry rate as a function of the ratio of these peptides. The best correlations with A β deposition were rate of A β_{40} entry and the ratio of A β_{40} /A β_{42} .

20 [0060] Figures 5 A and B show an alternate presentation of the data for plasma levels of A β_{40} 24 hours and 1 hour after m266 injection. When the mice were grouped according to low, medium, or high A β coverage in the hippocampus, the animals with low A β deposition could be completely distinguished from those with high deposition as a function of the level of plasma A β_{40} .

Example 2

25 [0061] In a study similar to that set forth in Example 1, a cohort of 49 homozygous APP V717F mice were used. Before and after injection of 500 μ g IV of m266, plasma samples were obtained at 5 minutes, 1 hour, 3 hours, 6 hours and 24 hours and levels of A β_{40} and A β_{42} were assessed as described in Example 1. The mice were sacrificed after 24 hours and 1 hemisphere was assessed for the percentage of the area of the hippocampus or cingulate cortex occupied by A β peptide (using quantitative A β immunofluorescence staining) and the area occupied by amyloid (by thioflavine-S (amyloid) staining). The regions from the other hemisphere were assessed for A β peptide by ELISA.

30 [0062] The Pearson correlation coefficient (Pearson r) and significance (P value) were determined between plasma A β values (pre and post injection of m266) and hippocampal A β or amyloid load using GraphPad Prism software (version 3.00 for Windows, San Diego, USA). A β load is defined as the percentage area of the hippocampus covered by A β -immunoreactive deposits. Amyloid load is defined as the percentage area of the hippocampus covered by thioflavine-S positive deposits. Correlations were also determined between the plasma A β accumulation over 24 hours (area under curve, AUC) and hippocampal A β load or amyloid load.

35 [0063] Figure 6 shown the results obtained. Briefly, it was found that the base line levels (prior to injection) of A β_{40} , A β_{42} and the calculated A $\beta_{40}/42$ ratio prior to injection with m266 did not correlate with percentage A β or amyloid deposition. However, following administration of m266, there were significant correlations between plasma A β_{40} , A β_{42} , and A $\beta_{40}/42$ ratio with both A β and amyloid burden in the hippocampus and cingulate cortex.

40 [0064] Statistical analysis of the results permits accurate prediction of hippocampal A β load in these mice based on plasma A β_{40} levels 24 hours following m266 injection.

9. The method of claim 6, wherein the humanized antibody or fragment thereof comprises a light chain comprising a variable region of SEQ ID NO:7 and a heavy chain comprising a variable region of SEQ ID NO:14.
10. The method of claim 1, wherein said antibody is a fragment.
11. The method of claim 1, wherein the antibody is a single-chain antibody.

Patentansprüche

1. Verfahren zur Diagnose von präklinischer oder klinischer Alzheimerschen Krankheit, umfassend:

(a) Messen von entweder

- (i) dem Gehalt an $A\beta_{40}$;
(ii) dem Gehalt an $A\beta_{42}$; oder
(II) dem Verhältnis von $A\beta_{40}/A\beta_{42}$

oder von mehreren davon;

in einer Blutprobe eines Subjekts, die in einem Zeitintervall nach Verabreichung einer Menge an einem Antikörper an dieses Subjekt erhalten wurde, wobei der Antikörper ein innerhalb den Positionen 13-28 von $A\beta$ enthaltenes Epitop spezifisch bindet oder der Antikörper ein $A\beta$ -Peptid aus seiner gebundenen zirkulierenden Form im Blut sequestriert und die Clearance von löslichen und gebundenen Formen von $A\beta$ im zentralen Nervensystem in Plasma verändert, wobei die Menge effektiv ist, die Gehalte an zirkulierenden $A\beta$ -Peptiden im Blut des Subjekts zu verändern, wenn das Subjekt sich in einem präklinischen oder klinischen Stadium der Alzheimerschen Krankheit befindet; und

(b) Vergleichen des Gehalts an $A\beta_{40}$, $A\beta_{42}$ oder des Verhältnisses von $A\beta_{40}/A\beta_{42}$ im Subjekt mit einem Kontrollwert der Gehalte, wobei Gehalte von $A\beta_{40}$, $A\beta_{42}$ oder des Verhältnisses von $A\beta_{40}/A\beta_{42}$ im Objekt, die im Vergleich zu den Kontrollgehalten oder dem Kontrollverhältnis erhöht sind, das Subjekt als eines identifizieren, das sich in einem präklinischen oder klinischen Stadium der Alzheimerschen Krankheit befindet.

2. Verfahren nach Anspruch 1, wobei das Zeitintervall weniger als 1 Woche beträgt.
3. Verfahren nach Anspruch 1, wobei, das Zeitintervall weniger als 24 Stunden oder gleich 24 Stunden beträgt.
4. Verfahren nach Anspruch 3, wobei das Zeitintervall weniger als 3 Stunden oder gleich 3 Stunden beträgt.
5. Verfahren nach Anspruch 1, wobei die Verabreichung mittels Injektion der Antikörper erfolgte.
6. Verfahren nach Anspruch 1, wobei das Subjekt menschlich ist und der Antikörper ein humanisierter Antikörper oder ein Fragment davon ist.
7. Verfahren nach Anspruch 6, wobei der humanisierte Antikörper oder das Fragment davon eine leichte Kette von SEQ ID Nr. 11 und eine schwere Kette von SEQ ID Nr. 12 umfasst.
8. Verfahren nach Anspruch 6, wobei der humanisierte Antikörper oder das Fragment davon eine leichte Kette von SEQ ID Nr. 11 und eine schwere Kette von SEQ ID Nr. 16 umfasst.
9. Verfahren nach Anspruch 6, wobei der humanisierte Antikörper oder das Fragment davon eine leichte Kette, die eine variable Region von SEQ ID Nr. 7 aufweist, und eine schwere Kette umfasst, die eine variable Region von SEQ ID Nr. 14 aufweist.
10. Verfahren nach Anspruch 1, wobei der Antikörper ein Fragment ist.
11. Verfahren nach Anspruch 1, wobei der Antikörper ein Einzelketten-Antikörper ist.

Revendications

1. Procédé de diagnostic de la maladie d'Alzheimer au stade pré-clinique ou clinique, comprenant :

5 (a) la mesure d'au moins :

- (i) la concentration d'A β ₄₀
- (ii) la concentration d'A β ₄₂ ou
- (iii) le rapport A β ₄₀/A β ₄₂

10 dans un échantillon de sang d'un sujet, prélevé à un certain intervalle de temps après avoir administré audit sujet une certaine quantité d'un anticorps qui se lie spécifiquement à un épitope contenu au sein des positions 13-28 d'A β ₄₀ ou d'un anticorps qui séquestre le peptide A β de sa forme liée, circulante, dans le sang et altère la clairance plasmatique des formes soluble et liée d'A β dans le système nerveux central, dans lequel ladite

15 quantité est efficace pour altérer les concentrations des peptides A β circulant dans le sang dudit sujet quand ledit sujet est dans un stade pré-clinique ou clinique de la maladie d'Alzheimer; et
(b) la comparaison de la concentration d'A β ₄₀, d'A β ₄₂ ou du rapport A β ₄₀/A β ₄₂ chez ledit sujet à une valeur témoin desdites concentrations, dans laquelle l'augmentation des concentrations d'A β ₄₀, d'A β ₄₂ ou du rapport A β ₄₀/A β ₄₂ chez ledit sujet par rapport aux concentrations témoins ou au rapport témoin identifie ledit sujet

20 comme étant à un stade pré-clinique ou clinique de la maladie d'Alzheimer.

2. Procédé selon la revendication 1, dans lequel ledit intervalle de temps est inférieur à une semaine.

3. Procédé selon la revendication 1, dans lequel ledit intervalle de temps est inférieur ou égal à 24 heures.

25

4. Procédé selon la revendication 1, dans lequel ledit intervalle de temps est inférieur ou égal à 3 heures.

5. Procédé selon la revendication 1, dans lequel ladite administration est faite par injection desdits anticorps.

30 6. Procédé selon la revendication 1, dans lequel le sujet est humain et l'anticorps est un anticorps humanisé ou un fragment de celui-ci.

7. Procédé selon la revendication 6, dans lequel l'anticorps humanisé ou le fragment de celui-ci comprend une chaîne légère de SEQ ID NO:11 et une chaîne lourde de SEQ ID NO:12.

35

8. Procédé selon la revendication 6, dans lequel l'anticorps humanisé ou le fragment de celui-ci comprend une chaîne légère de SEQ ID NO:11 et une chaîne lourde de SEQ ID NO:16.

9. Procédé selon la revendication 6, dans lequel l'anticorps humanisé ou le fragment de celui-ci comprend une chaîne légère comprenant une région variable de SEQ ID NO:7 et une chaîne lourde comprenant une région variable de SEQ ID NO:14.

40

10. Procédé selon la revendication 1, dans lequel ledit anticorps est un fragment.

45 11. Procédé selon la revendication 1, dans lequel l'anticorps est un anticorps à chaîne unique.

摘要(译)

临床前和临床阿尔茨海默氏病的诊断测试基于血浆A β 40，A β 42的水平，它们的比率或在施用整合A beta的抗体后的进入率。这些参数中任何一个相对于控制值的改变都可以识别出临床前或临床的阿尔茨海默氏病。
